Bowel Obstruction Due to Meckel’s Diverticulum: A Case Report

By Mounir Bouali, Kenza Benjelloun Touimi, Abdelilah El Bakouri, Khalid El Hattabi, Fatim-Zahra Bensardi & Abdelaziz Fadil

Abstract- Meckel's diverticulum is the most prevalent congenital abnormality of the gastrointestinal tract. This anomaly is due to the incomplete obliteration of the omphalomesenteric duct during the 7th week of gestation and is classically located 2 feet proximal to the ileocecal valve (1).

While most of the population may be asymptomatic, clinical manifestation, including gastrointestinal bleed and intestinal obstruction, can emerge. Despite the frequency of Meckel's diverticulum, it is commonly misdiagnosed due to its mimicry of appendicitis. We reported in our case a patient with bowel obstruction.

Meckel’s diverticulum was discovered during surgery.

Keywords: meckel’s diverticulum, bowel obstruction.

Abstract - Meckel’s diverticulum is the most prevalent congenital abnormality of the gastrointestinal tract. This anomaly is due to the incomplete obliteration of the omphalomesenteric duct during the 7th week of gestation and is classically located 2 feet proximal to the ileocecal valve (1).

While most of the population may be asymptomatic, clinical manifestation, including gastrointestinal bleed and intestinal obstruction, can emerge. Despite the frequency of Meckel’s diverticulum, it is commonly misdiagnosed due to its mimicry of appendicitis. We reported in our case a patient with bowel obstruction.

Meckel’s diverticulum was discovered during surgery.

Keywords: meckel’s diverticulum, bowel obstruction.

I. Introduction

Meckel’s diverticulum is the most common congenital malformation of the gastrointestinal tract.

Due to the rarity of cases in adults, it is still misdiagnosed preoperatively.

We describe in our case a patient with bowel obstruction due to meckel’s diverticulum.

II. Case Presentation

Patient was 41-year-old man. He had no medical history.

He was referred to our emergency, he had symptoms of intestinal obstruction: he couldn’t have a pass gas, he noticed stomach pain and a swollen belly. He had no external gastrointestinal bleeding.

On examination, he was afebrile, with normal respiratory rate and normal resting heart rate.

On physical exam, the patient’s abdomen was distended, tympanic on percussion.

Digital rectal exam was normal with no hematochezia.

Abdominal CT scan showed small and large bowel distension with a caliber disparity in the right iliac fossa and air-fluid levels.

On the same admission day, the patient was transferred to the operating room. The patient and his family gave their approval to do surgery. During laparotomy under general anesthesia, the exploration showed a Meckel's diverticulum adhering to the abdominal wall, located at 60 cm from the ileocecal valve responsible for a small bowel volvulus which is the site of perforative lesions and also responsible for distension of the small bowel measuring 5 cm.

We proceeded to 10 cm small bowel resection carrying a Meckel's diverticulum and perforative lesions and end to end bowel anastomosis. The post-operative care was simple, he was discharged from hospital on postoperative day 5, after allowing liquid feeding without incident.

III. Discussion

Meckel’s diverticulum was named after Johann Friedrich Meckel, who described its anatomy and embryology in 1809 (2).

This anomaly is due to the incomplete obliteration of the omphalomesenteric duct during the 7th week of gestation and is classically located 2 feet proximal to the ileocecal valve (1).

Meckel’s diverticula are lined with heterotopic mucosa in up to 60% of cases in the following manner: gastric mucosa, 62%; pancreatic, 6%; both gastric and pancreatic, 5%; jejunal, 2%; Brunner’s glands, 2%; and gastric and duodenal, 2% (3).

Most of the population may be asymptomatic. Bleeding from Meckel’s diverticulum due to ectopic gastric mucosa is the most common clinical presentation, especially in younger patient, but it is rare
The complications in adults include: obstruction; intussusception; ulceration; haemorrhage; and, rarely, vesicodiverticular fistulae and tumours (4).

The diverticulum is occasionally identified incidentally on imaging studies and may be found during the course of a laparotomy performed for other reasons. The preferred diagnostic method is laparoscopy in doubtful cases. However, laparoscopy is not an initial step of diagnostic modalities as it is more invasive compared to conventional imaging methods (5).

Plain X-ray, barium studies and computed tomography (CT) scans are seldom beneficial for a preoperative diagnosis of the diverticulum. The typical appearance of an intestinal obstruction may be demonstrated by plain abdominal radiographs. When distension develops in a diverticulum, diagnosis may be established due to a gas-filled viscous appearance in the right iliac fossa or middle abdomen region. If a perforation develops as a complication, the findings of pneumoperitoneum may be seen on upright chest and plain abdominal radiographs. Characteristically, the diverticulum is delineated as a contrast-filled out pouching which has a junctional fold pattern and is seated on the anti-mesenteric margin of the small bowel (5).

Ultrasoundography, although not specific enough for imaging this condition, may reveal a tubular diverticulum swollen with fluid in a region away from the cecum, invagination, segmental thickening of the bowel walls, swelling of diverticular wall and pelvic abscess (6).

Capsule endoscopy is a novel technological tool for the examination of the small bowel in a noninvasive and simple manner. It has been proved in a number of studies that capsule endoscopy has the capability to detect small intestine lesions in cases with obscure gastrointestinal hemorrhage. The entire small intestine can be examined by both double-balloon enteroscopy and capsule endoscopy. For the detection of hemorrhagic lesions in the small bowel, other studies proved that the efficacy of both capsule endoscopy and double-balloon enteroscopy is similar. However, capsule endoscopy is contra-indicated and also difficult in cases under ten years of age. Furthermore, it is relatively simple to reach via the retrograde double-balloon enteroscopy method, as the distance of the Meckel's diverticulum is generally closer than a meter from the ileocecal valve (7).

The treatment for Meckel's diverticula is shown in this algorithm (8):

**Figure 6:** The treatment algorithm of Meckel's diverticulum

IV. Conclusion

Meckel's diverticulum is the most prevalent congenital abnormality of the gastrointestinal tract. Most of the population may be asymptomatic. A good level of knowledge of the clinical, embryological, radiological and pathological features of Meckel's diverticulum will enable a rapid and proper diagnosis of patients, thereby allowing treatment via a timely surgical intervention.
