The Relation of Serum High-Sensitive C-Reactive Protein to 1 Serum Lipid Profile, Vitamin D and Other Variables in a Group 2 of Hypertensive Patients in Erbil-Iraq 3 Salam Naser Zangana¹ 4 ¹ Hawler Medical University 5 Received: 12 December 2015 Accepted: 2 January 2016 Published: 15 January 2016 6

Abstract 8

Background and objectives: Hypertension is an established risk factor for atherosclerosis. 9 Elevated levels of high-sensitive C-reactive protein (hs-CRP) were detected in hypertensive 10 patients. Recent studies suggest a link between high-sensitive C-reactive protein (hs-CRP) 11 and atherosclerosis in hypertension. Growing evidence suggests that vitamin D affects the 12 cardiovascular system The objective of this study was to assess the relationship of hs-CRP to 13 lipid profile, vitamin D and other variables in hypertensive patients in Erbil- Iraq. Subjects 14 and Methods: This cross-sectional study was conducted on two-hundred adults (130 15 hypertensives and 70 normotensives). The participants were classified into three groups 16 according to their BP measurements as normotensive (group I), stage I hypertension (group 17 II) and stage II hypertension (group III). Serum hs-CRP, lipid profile, vitamin D levels, and 18 other variables were evaluated in all studied groups. Results: Hs-CRP level was significantly 19 higher in hypertensives as compared to normotensives (P < 0.001). The means of total 20 cholesterol (TC), triglyceride (TG) and low-density lipoprotein (LDL) were significantly 21 higher, while the mean of high-density lipoprotein (HDL) was significantly lower in 22 hypertensives than in normotensives (P < 0.001). The mean of vitamin D was significantly 23 lower in hypertensives than in normotensives (P < 0.001). Hs-CRP was positively correlated 24 with TC, TG, and LDL but inversely correlated with HDL and vitamin D. Conclusions: 25 Higher levels of hs-CRP were detected in hypertensive patients than normotensives. The 26 higher hs-CRP levels were significantly correlated with higher grades of hypertension. Hs-CRP 27 was positively correlated with lipid profile and inversely correlated with vitamin D. Increased 28 levels of hs-CRP in hypertension may suggest a role of inflammation in hypertension. Hs-CRP 29 estimation may be recommended in evaluation of all hypertensive patients. Subjects and 30 Methods: This cross-sectional study was conducted on two-hundred adults (130 hypertensives 31 and 70 normotensives). The participants were classified into three groups according to their 32 BP measurements as normotensive (group I), stage I hypertension (group II) and stage II 33 hypertension (group III). Serum hs-CRP, lipid profile, vitamin D levels, and other variables 34 were evaluated in all studied groups. 35

Abstract-Background and objectives: Hypertension is an established risk factor for atherosclerosis. Elevated
levels of high-sensitive C-reactive protein (hs-CRP) were detected in hypertensive patients. Recent studies suggest
a link between high-sensitive C-reactive protein (hs-CRP) and atherosclerosis in hypertension. Growing evidence
suggests that vitamin D affects the cardiovascular system The objective of this study was to assess the relationship
of hs-CRP to lipid profile, vitamin D and other variables in hypertensive patients in Erbil-Iraq.

Subjects and Methods: This cross-sectional study was conducted on two-hundred adults (130 hypertensives and 70 normotensives). The participants were classified into three groups according to their BP measurements as normotensive (group I), stage I hypertension (group II) and stage II hypertension (group III). Serum hs-CRP, lipid profile, vitamin D levels, and other variables were evaluated in all studied groups.

Results: Hs-CRP level was significantly higher in hypertensives as compared to normotensives (P <0.001). The
means of total cholesterol (TC), triglyceride (TG) and low-density lipoprotein (LDL) were significantly higher,
while the mean of high-density lipoprotein (HDL) was significantly lower in hypertensives than in normotensives
(P <0.001). The mean of vitamin D was significantly lower in hypertensives than in normotensives (P<0.001).
Hs-CRP was positively correlated with TC, TG, and LDL but inversely correlated with HDL and vitamin D.

Conclusions: Higher levels of hs-CRP were detected in hypertensive patients than normotensives. The higher hs-CRP levels were significantly correlated with higher grades of hypertension. Hs-CRP was positively correlated with lipid profile and inversely correlated with vitamin D .Increased levels of hs-CRP in hypertension may suggest a role of inflammation in hypertension. Hs-CRP estimation may be recommended in evaluation of all hypertensive patients.

⁵⁹ 1 I. Introduction

ypertension is an established major independent risk factor for development of atherosclerosis and multiple 60 61 cardiovascular diseases worldwide. 1 According to the 2006 Iraqi national survey for chronic disease risk factors, 62 40.4% of the Iraqi adult populations have elevated blood pressure. 2 Many recent studies correlate between hypertension and inflammation. 3 New proof indicates that vascular inflammation may have a role in the 63 initiation and /or development of hypertension. 4 Several researchers have noticed higher high-sensitive C-64 reactive protein (hs-CRP) levels in patients with hypertension. 5 Vitamin D deficiency or insufficiency is a 65 common condition that affects up to one-half of otherwise healthy middle aged to elderly population. 6 Although 66 vitamin D deficiency involves mainly musculoskeletal system, growing evidence suggests that vitamin D affects 67 the cardiovascular system also. 7 High concentrations of CRP might reduce nitric oxide production in endothelial 68 cells, leading to vasoconcentration and increase blood pressure. Endothelial dysfunction and inflammation were 69 associated with arterial stiffness. 8 Hs-CRP ,an acute phase reactant protein, is a proinflammatory atherogenic 70 marker which can be an early cardiac risk predictor. 9 A hs-CRP test measures low levels of CRP using laser 71 nephelometry. The test gives a sensitivity results down to 0.04 mg/L. The American Heart Association and U.S. 72 Centers for Disease Control and Prevention have defined risk groups as follows: low: hs-CRP level under 1.0 73 mg/L, average: between 1.0 and 3.0 mg/L, and high: above 3.0 mg/L. 10,11 To date, and up to our knowledge, 74 there was no previous study done regarding the same subject in Erbil city. The objective of this study was to 75 assess the correlation between hs-CRP levels to serum lipid profile and other variables in a group of hypertensive 76 patients in Erbil city-Iraq. 77

⁷⁸ 2 II. Patients and Methods

This cross-sectional study was conducted in Rizgary teaching hospital between July 2015 and July 2016. A total of 200 participants (130 participants with essential hypertension and additional 70 normotensives, as control group) were enrolled in the study. According to blood pressure (BP) measurements, The participants were classified into three groups; Group I (normotensive participants, SBP ?120 mmHg, and /or DBP ?80 The inclusion criteria were patients with essential hypertension, age ? 18 years and of both genders.

The exclusion criteria were patients with secondary hypertension (diabetic nephropathy, polycystic kidney disease, renovascular hypertension), Cushing syndrome, thyroid disease, chronic renal failure, patients with primary hyperparathyroidism, malabsorption, osteomalcia or osteoporosis, patients on medications like anticonvulsants, glucocorticoids and vitamin D supplements.

BMI (Body Mass Index, weight/height 2) was calculated according to a standard definition. 12 Based on 88 recommendations of the Eighth Report of the Joint National Committee on Prevention, Detection, Evaluation, 89 and Treatment of High Blood Pressure (JNC 8) 13, hypertension was defined as systolic blood pressure ?140 90 91 mmhg and diastolic blood pressure? 90 mmhg for adults aged 18 years and less than 60 years, and systolic blood 92 pressure ? 150 or diastolic ? 90 in general population ? 60 years. Blood pressure measurements used in this 93 study were taken with a mercury sphygmomanometer. Measurements were made to the nearest 2mmhg, in the 94 sitting position with the arm supported, and repeated after 5 minutes' rest if the first recording is high. We will take 2 measurements at each visit. 95

Transthoracic echocardiographic examinations were performed in the left lateral position. Standard Mmode, 2-Dimensional and Doppler echocardiographies were performed using (Brand GE Vivid E9 -2009) echocardiography machine. LV end-diastolic diameter (LVDd), LV end-systolic diameter(LVSd), left atrial (LA) and all other diameters were measured according to established standards of the American Society of Echocardiography. 14 ¹⁰⁰ LV mass (LVM) were calculated according to the Devereux formula 15 : LVM=1.04[(LVDd + IVSth +PWT) 3 -(LVDd) 3]-13.6. Thereafter, LV mass index(LVMI) was obtained by the following formula: LVM/body surface area (g/m 2) 16. In the presence of LVH, the LVM exceeds 134 grams in men and 110 grams in women per meter square body surface area (m 2 BSA).

Although a consensus regarding the optimal level of serum 25(OH) D has not yet been established, most 104 experts define vitamin D deficiency as a 25(OH) D level of < 20 ng/ml, vitamin D insufficiency as 21 to 29 ng/ml 105 and the optimal concentration of 25(OH) D is at least 30 ng/ml. 17 Estimation of serum lipid profile was done 106 by using automated biochemistry analyzer and according to standard methods. 18 Pulse pressure (PP) is the 107 difference between the systolic and diastolic pressure readings (PP= SBP-DBP). It is measured in millimeters of 108 mercury (mmHg). It represents the force that the heart generates each time it contracts. 19 The mean arterial 109 pressure (MAP) is a term used to describe an average blood pressure in an individual. It is defined as the average 110 arterial pressure during a single cardiac cycle. 19 MAP=DBP+1/3 PP. 111

The data were collected by interviewing the patients using a questionnaire designed by the researchers. The 112 questionnaire included information about socio-demographic data (age, gender, marital status,?), hypertension, 113 risk factors like hyperlipidemia, IHD, obesity, family history, others), and history of smoking and alcoholism. 114 Ethical considerations: The study protocol was approved by the ethics committee of the College of Medicine of 115 116 Hawler Medical University. This study was conducted by using an informed verbal consent from the patients prior 117 to participation in the study. The purpose of the study was carefully explained to each patient. Statistical analysis 118 of data: Data were analyzed using the statistical package for social sciences (SPSS, version 19). Student's t test for two independent samples was used to compare means. Correlation coefficient (r) was obtained to demonstrate 119 the correlations between variables. A 'P' value of ? 0.05 was considered as statistically significant. 120

¹²¹ 3 III. Results

The age and BMI were matched in all three groups of the study (P = 0.49 and 0.98, respectively). As expected, 122 SBP, DBP, PP and MAP values were significantly higher in hypertensive groups as compared to normotensive 123 group (P<0.001, for each). Statistically higher levels of TC, TG, LDL (P<0.001, for each) and lower level of 124 HDL (P<0.001) were found in hypertensives than in normotensives. IVS, PW, LVM, LVMI and RWT levels were 125 significantly higher (P < 0.001, for each) in hypertensives as compared to normotensives. We found also that 126 the mean of vitamin D level was significantly lower (7.61 ng/dl) and the mean of hs-CRP level was significantly 127 higher (2.75 mg/dl) in hypertensives than normotensives (17.3 mg/dl and 0.74 mg/dl respectively) (P<0.001, for 128 each), as shown in Table 1. 129

In Table 2, which compares between the two hypertensive groups and as expected, SBP, DBP, PP and MAP values were significantly higher (P<0.001, for each) in group III as compared to group II. There were no differences in both groups regarding serum lipid profile values (P=0.91, 0.87, 0.74 and 0.8 respectively), the same applies to EF (P=0.85). IVS, PW, LVM, LVMI, RWT and left atrium values were significantly higher in group III patients than in group II patients. Group III patients had significantly higher hs-CRP values (3.67 mg/dl) than group II patients (1.83 mg/dl) (P<0.001). Although the mean value of vitamin D was lower (6.9 ng/dl) in group III patients than in group II patients (8.32 ng/dl), but it was not statistically significant (P=0.5).

¹³⁷ 4 Volume XVI Issue III Version I

Hs-CRP correlated positively with SBP, DBP, PP, MAP, TC, TG, LDL, LVM, LVMI, and correlated negatively
 with HDL and vitamin D, as shown in Table 3.

¹⁴⁰ 5 IV. Discussion

In the present study, hypertensive patients had higher hs-CRP levels than normotensives. This indicates that inflammation might be associated with hypertension. This is compatible with other studies. Ki Chul Sung et al 20 and Sesso et al 21 found a positive relation between increasing levels of hs-CRP and risk of developing hypertension. But Bautista et al 22 in 2003 didn't find such association.

CRP has been reported to decrease nitric oxide production 8 and increases endothelin-1 and plasminogen 145 activator inhibitor-1 activity in endothelial cells 23 to induce vasoconstriction, platelet activation, and thrombosis. 146 In addition, CRP has shown to up regulate angiotensin receptor-1 and thus enhancing angiotensin-II activity 147 and this leads to rise in blood pressure. 24 In our study, hypertensive patients had abnormal lipid profile and 148 that was evident by the presence of high TC, TG and LDL levels and low HDL level. This is compatible with 149 other studies. Rasouli M et al 25 found higher cholesterol and TG levels in hypertension. In the Strong Heart 150 Study (2006) 26, an abnormal lipid profile was found in hypertensive American Indian population. Marco et 151 152 al 27 found that participants who were prehypertensives and later developed hypertension had higher levels of 153 TG and lower HDL levels. All these data suggest that vascular inflammation plays a role in pathophysiology of hypertension and may exacerbate the pro-atherogenic effects of hypertension. 154

In our study, elevated hs-CRP levels were associated with high PP. This result is compatible with Abramson et al 28 study which found such a positive association. Recent studies emphasize the possibility that arterial stiffening may precede the development of hypertension. Arterial stiffening was associated with many circulating inflammatory markers suggesting that inflammation may play a role in arterial stiffness. 29 If the blood vessel

becomes rigid in conditions such as arteriosclerosis or atherosclerosis, the pulse pressure would be very high. Some 159 evidence suggests that pulse pressure is a better predictor of clinical outcome than the systolic or diastolic blood 160 pressure alone. Several studies have identified that high pulse pressure causes more artery damage compared 161 to high blood pressure with normal pulse pressure. 30 Recent work suggests that a high pulse pressure is an 162 important risk factor for heart disease. A meta-analysis in 2000, which combined the results of several studies 163 of 8,000 elderly patients in all, found that a 10 mm Hg increase in pulse pressure increased the risk of major 164 cardiovascular complications and mortality by nearly 20%. 31 A positive association between high hs-CRP level 165 and high MAP was also found in the present study. Many other studies found the same relationship. 32,33 In the 166 present study, hs-CRP was positively related to LVM and LVMI, an echocardiographic marker of left ventricular 167 hypertrophy (LVH). This result is compatible with other previous studies 34 , which found that patients with 168 different involved target organ had different inflammatory degree, which hypertensive patients with LVH had the 169 highest hs-CRP levels. 170

Finally, in the present study, hs-CRP was negatively related to vitamin D level. Although vitamin D deficiency involves mainly musculoskeletal system, growing evidence suggests that vitamin D affects the cardiovascular system also. 7 Recent clinical studies showed that low levels of vitamin D are associated with a higher prevalence of hypertension and LVH. 35 Elevated hs-CRP and vitamin D deficiency are associated with inflammatory changes

175 that have been associated with cardiovascular events. 36

176 6 V. Conclusions

Higher levels of hs-CRP were seen in hypertensive patients than normotensives. The higher hs-CRP levels were significantly correlated with higher grades of hypertension. Hs-CRP was positively correlated to lipid profile and inversely correlated to vitamin D. Increased levels of hs-CRP in hypertension implies a role of inflammation in hypertension. Hs-CRP estimation may be recommended in evaluation of all hypertensive patients.
