Size of Hemorrhage on CT Scan and GC Scale use to Determine the Outcome of Hemorrhagic Stroke in Hypertensive Patients

By Milisha Lal, Nisha Gaur, Sumit Kamble, Harsh Chapadia, Sindhu Avula, Karthik Gangu, Kimmyben Patel & Abhishek Vadher

North Shore University hospital, United States

Abstract- Introduction: This study was to identify hypertensive Intracranial Hemorrhage with hematoma as well as the relation to various factors and outcomes.

Objective: To find the correlation between the site and size of hemorrhage, GCS score, and the outcome.

Methods: This is a prospective observational trial. The study consists of 65 patients with Intracranial hemorrhage, presenting with the criteria and symptoms in order to correlate with the GCS score and GC scale. This study was conducted at Shree Sayaji General Hospital, Baroda during December 2013 to November 2014. The GC scale was used to assess the outcome. The GC score was used for distribution of the patients with presenting symptoms. CT scan of the head was also used to identify the site of the hemorrhage and the size of the hemorrhage.

Results: The increase in hematoma volume in the study shows the high percentage of mortality. This shows that the lower the GC score is worse for prognosis than a higher GC score of >14 .

Conclusion: Our results show that a low GC score and high size of the bleed can significantly affect the prognosis.

I. INTRODUCTION

Cerebrovascular accident or stroke is defined as an acute loss of focal and at times global (applied to patient in deep coma and those with subarachnoid hemorrhage) cerebral function, the symptoms lasting more than 24 hours or leading to death with no apparent cause other than that of vascular origin(WHO). Stroke can be ischemic or hemorrhagic and this is due to lack of blood flow to the brain and bleeding in the brain tissue respectively. Stroke can manifest with symptoms like loss of sensory or motor functions on one side of the body. It can also manifest as loss of vision, inability to speak or understand^{1,2}. Cerebrovascular accidents represent third commonest cause of death worldwide. In United States, every year around 795000 people suffer from stroke and 130000

people die from stroke which is equal to 1 in every 20 deaths³. 87% of the stroke are due to ischemia and the rest 13% are due to hemorrhage⁴. The death due to stroke annually in United States is 130000 which is equal to 1 in every 20. Hypertension is the most important risk factor for stroke⁵. Hemorrhagic stroke has higher morbidity and mortality when compared to ischemic stroke. Hemorrhagic stroke is due to bleeding either in the brain or in the subarachnoid space⁶. Identifying high risk patients for development of Intracerebral Hemorrhage and to institute vigorous treatment in these patients is vital for prevention of Intracerebral Hemorrhage. Factors such as age, the score on Glasgow coma scale, the size of hematoma, rupture of hemorrhage in ventricle, midline shift and pulse pressure have been identified as determinant of outcome. The clinical and the CT correlates may contribute to the ultimate prognosis of these patients. By studying prognostic parameters of hypertensive Intracerebral Hemorrhage we can identify high risk patients, who are prone to develop Intracerebral Hemorrhage. Therefore, we can offer prompt and right treatment to patients with Intracerebral Hemorrhage.

II. OBJECTIVES

1. To study the prognosis of patients with hypertensive intracerebral hemorrhage clinically.
2. To study prognosis of patients of hypertensive intracerebral hemorrhage with help of CT scan brain.

III. MATERIALS AND METHODS

This is a prospective observational study with 65 patients. Follow up was done after one month of the patients included in the study. All CT proven hypertensive intracerebral haemorrhage patients admitted included in study with systolic BP >140mm of Hg and diastolic BP >90 mm of Hg. Patients having haemorrhage as a result of head injury, bleed in primary or secondary brain tumours, haemorrhage within a cerebral infarct, bleeding secondary to arteriovenous malformation and aneurysms were excluded. A thorough General examination was undertaken in particular for Glasgow coma scale, Vital examination

including temperature, pulse, respiratory rate, and blood pressure was noted, Peripheral signs of atherosclerosis like arcus senilis, locomotor, brachialis, thickened vessel wall, vascular bruit, xanthomas and xanthelesmas. Detailed Nervous System examination was done including fundoscopy. After history and examination investigations like Complete blood count, Urine albumin, sugar, urine microscopy, Random blood sugar on admission, Serum urea, creatinine levels as renal function test, Lipid Profile: total cholesterol, Triglyceride, LDL level, HDL Level, VLDL, total cholesterol/HDL ratio, LDL/HDL ratio were done. ECG to find out if signs of ischemia, arrhythmia, hypertrophy are present or not. In CT scan a preliminary lateral topogram of the cranium was obtained. Serial transaxial scans were then performed with OM line as reference and employing 10mm and 5 mm sections. 5/5 mm sections were performed through posterior fossa. CT Head was carried out to know the site, size, volume, mass effect, ventricular extension, cerebral edema of intracerebral hemorrhage. All data was analysed using appropriate statistical tests. A p value of $<.05$ will be considered significant. Data was entered in excel sheet and analyzed by EPI INFO software.

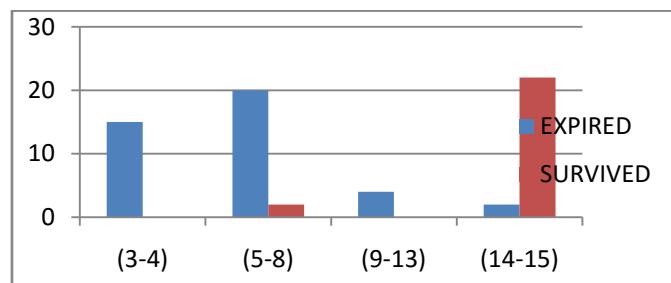

IV. RESULT AND ANALYSIS

Table -1 : Age Distribution of Hypertensive Intracerebral Hemorrhage In Study

Age group (yrs)	Survived	Expired	Total
30-39	2	0	2
40-49	5	2	7
50-59	5	6	11
60-69	6	15	21
70-79	4	9	13
80-89	2	6	8
>90	0	3	3
Total	24	41	65

Table-3 : Distribution of Patients With Gc Score and Correlation with Outcome

GC Score	Total Cases	Survived (%)	Expired (%)	P value
3-4	15(23.1%)	-	15 (100%)	0.002
5-8	22(33.8%)	2(9.1%)	20 (90.90%)	
9-13	4(6.1%)	-	4 (100%)	
14-15	24(36.9%)	22(91.7%)	2 (8.3%)	
TOTAL	65	24(36.9%)	41 (63.1%)	

Two thirds of the stroke are in patients with age greater than 65⁷. In our study, there were 45 patients with age > 60 which is 69.23%.

Table-2 : Distribution According To Presenting Symptoms

Symptoms	No.of cases	Percentage
Weakness of limb		
- Hemiplegia	41	46.15%
- single limb	2	3.0%
Altered sensorium	40	61.5%
Headache	31	47.69%
Vomiting	31	47.69%
Convulsion	7	10.76%
Sensory symptoms	-	-
Vertigo	2	3.0%
Apraxia	1	1.5%

Maximum patients presented with altered sensorium (61.5%). Headache was present in 47.69% patients and vomiting was present in 47.69%. Hemiplegia was present in 46.1% patients.

In our study 40 (61.5%) patients were known case of hypertension, in which 22 (55%) patients expired. Our study is showing higher mortality (76%) in first time diagnosed hypertensive patients than in patients who were known case of hypertension.

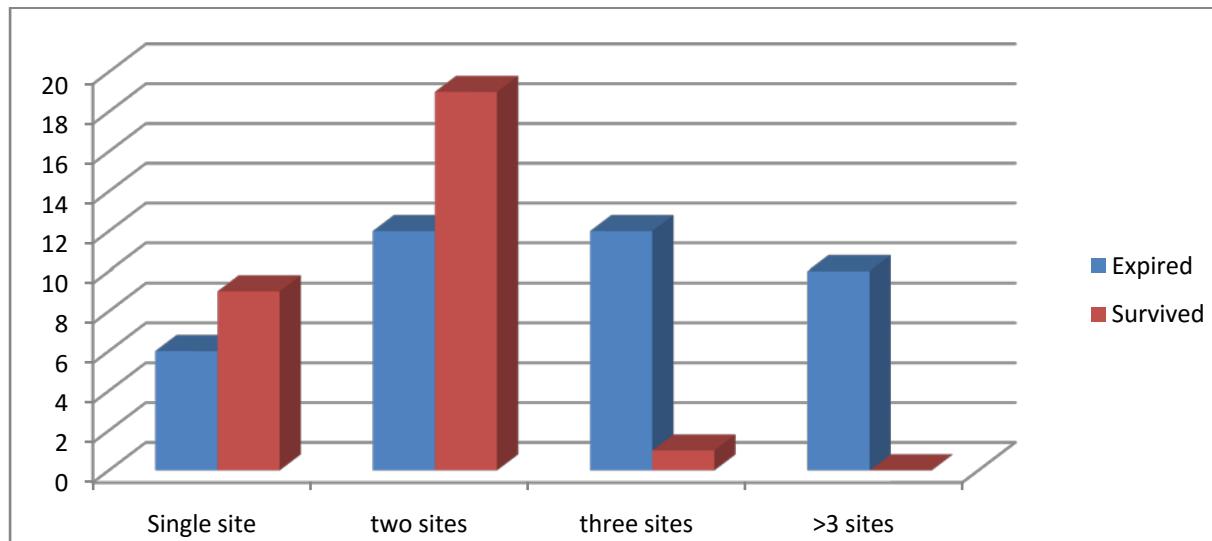

In our study 14 (21.5%) patients were known case of Diabetes in which 12 (85.7%) patients expired. So higher mortality was seen in patients with Diabetes Mellitus (85.7%) than in patients without Diabetes (56.8%). In our study 37(56.9%) were smokers and higher mortality (70.2%) was seen amongst smokers than nonsmokers(53.6%).

In our study maximum patients were in GC score 14-15 (53.3%). GC Score 3-4, 5-8, 9-13 had 100%, 90.9%, 100% mortality respectively, but GC Score 14-15

had only 8.5% mortality. This shows that prognosis (mortality) is worse with lower GC Score (p value = 0.002). This is statistically significant.

Table-4: Correlation between Site of Hemorrhage, Gcs Score and Outcome

Site of Hemorrhage	NO. of PT	GCS Score				Expired
		3-4	5-8	9-13	14-15	
Single site of hemorrhage:						
• Cerebral cortex	5	-	2	-	3	2(40%)
• Thalamus	2	-	1	-	1	1(50%)
• Internal capsule	-	-	-	-	-	
• Putamen	-	-	-	-	-	
• Basal ganglion	2	-	-	-	-	1(50%)
• Cerebellum	4	1	2	-	1	2(50%)
Total patients	13(20%)	1(7.7%)	5(38.4)	-	7(53.8%)	6(46.2%)
Two site of hemorrhage:						
• Fronto-temporal	5		2		1	2(40%)
• Temporo-parietal	2		2			2(100%)
• Frontal-parietal	3	2	1			3(100%)
• Thalamus+internal capsule	15		2	1	12	3
• Basal ganglia+internal capsule	5	1				1
• Pons+mid brain	1	1	1		3	1
Total	31(47.7%)	4(12.9%)	8(25.8%)	1(3.2%)	16(51.6%)	13(18.46%)
Three site of hemorrhage:						
• Thalamus-basal ganglia-internal capsule	3	1	2			3
• Frontal-parieto-temporal	6	4	1	1		5
• Frontal+thalamus+internal capsule	1	1				1
• Basal ganglia+thalamus+midbrain	3	3				3
Total	13(20%)	9(69.2%)	3(23%)	1(7.6%)		12(92.3%)
>3 sites of hemorrhage	10(15.4%)	3(30%)	6(60%)	1(10%)		10(100%)

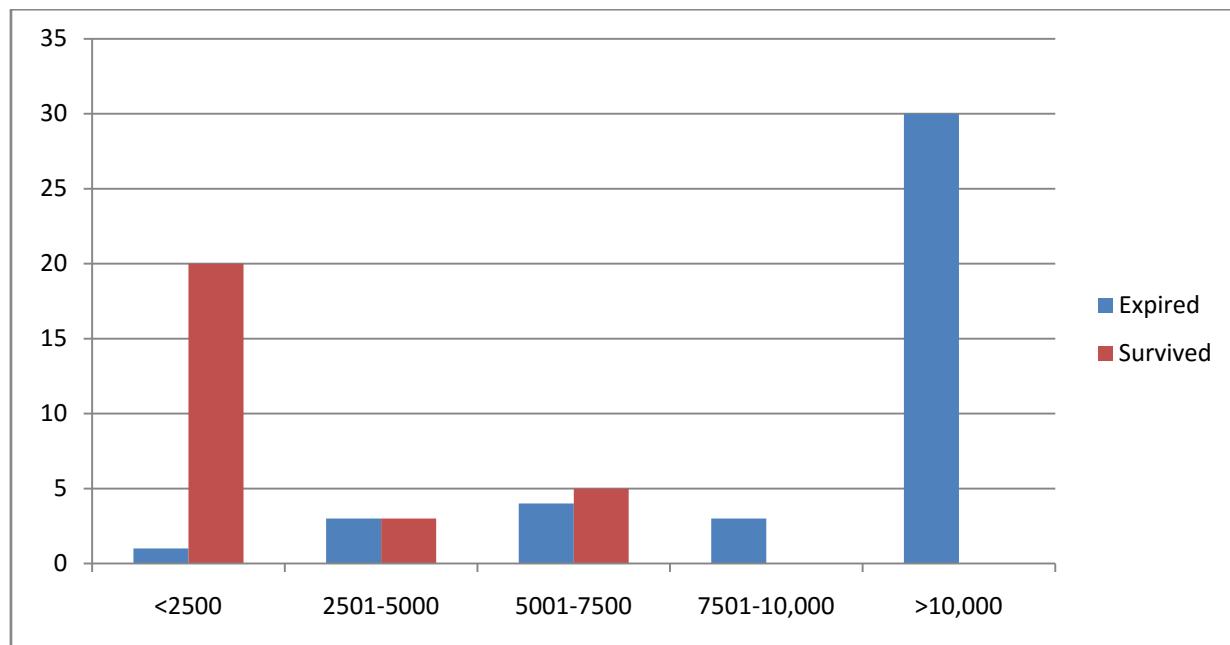

In our study patients with single site hemorrhage were 13(20%) with 46.2% mortality, 46.6% with GC score of 14-15 at the time of presentation. With three sites of hemorrhage 69.2 % patients were in GC score 3-4 and 92.3 % patients expired. With > 3 sites there was 100% mortality. So in our study with increasing sites of hemorrhage there is decreasing GC

score at presentation with increasing mortality trend (p value= 0.07). Here, as p value is >0.05 , this is not statistically significant. But as per some studies, brain stem hematoma, intraventricular extension of bleed and ventricular compression along and with midline shift are associated with early mortality in intracranial hemorrhage⁸.

Table-5: Size of Hemorrhage Versus Outcome

Volume of Hemorrhage(mm ³)	NO. Of Cases	NO. Of Patients Expired(%)	P value
<2500	21(32.3%)	1(4.1%)	0.0001
2501-5000	6(9.2%)	3(50%)	
5001-7500	5(7.6%)	4(80%)	
7501-10000	3(4.6%)	3(100%)	
>10000	30(46.15%)	30(100%)	

In our study maximum no. of patients had hematoma volume >10,000 mm³ - 30(46.15%) followed by 21 (32.3%) patients with volume <2500 mm³. Mortality is rising with increasing volume of hemorrhage in the study. There was 100% mortality with hematoma volume >7500mm³. P value was 0.0001 and this shows that the result was statistically significant. As per some studies, when the size of hematoma is >30 cm³, the morbidity and mortality increases significantly⁸.

V. DISCUSSION

As per age distribution, in our study, 100% mortality was noted in age group 70-79 yrs., 80-89 yrs. and >90 yrs. In our study for sex distribution, out of 65 patients, 55.3 % were males and 44.6% were females. Thus the ratio of male to female was 1.2:1. There was no significant association was found in male and female sex and poor outcome. (p value-0.497). For history of hypertension, in our study 61.5% were known case of hypertension, out of them 55% patients expired. Rest 38.4% patients were freshly detected cases of hypertension. Our hospital gets patients from lower socioeconomic strata with poor education. Our history for Diabetes Mellitus shows out of 65 patients, 21.5% patients had H/O diabetes, out of which 85.7 % expired. The GC score established significant correlation between the Glasgow coma scale on admission and poor outcome. (p=0.002). In our study for site of

hematoma, high mortality was not significantly associated with No. of sites of hemorrhage (p=0.07). However, the increasing No. of hemorrhages is associated with increasing mortality. Most patients had multiple sites of hemorrhage at the time of presentation. Therefore, prognosis on the basis of site (basal ganglia, thalamus, lobar, brain stem, cerebellar) was not possible. The volume of hemorrhage study shows the volume of intracerebral hemorrhage >10,000 mm³ is considered a severe stroke and proven as poor prognostic parameter for 30 days' mortality outcome. (p value =0.0001).

VI. CONCLUSION

Glasgow coma scale on admission is significant for poor prognosis. Number of sites of hemorrhage in a CT scan is not significant with poor outcome. The volume of the hemorrhage is significant for poor outcome of stroke.
