*Jahangir Nagar University*

**Abstract:** The worldwide demand for citric acid is increasing with the rising population and industrialization. The growing demand for citric acid and the need for alternative materials as substrates in the recent years have led to the choice of a novel and economically viable substrate, namely jackfruit (outer portion) and molasses for citric acid biosynthesis. Hydrolysis these substrates with 0.05N HCl followed by fermentation using two isolates of *Aspergillus niger* were investigated for citric acid production under submerged culture condition in a period of 15 days. The products of the microbial metabolism namely residual sugar, total titratable acidity (TTA), citric acid, and biomass contents were determined periodically. Maximum citric acid production was found after 12 days of fermentation for both isolates, namely *Aspergillus niger* CA16, the parent strain and gamma ray induced mutant *Aspergillus niger* 79/20. Citric acid production was found highest in the absence of Prescott salt by *Aspergillus niger* CA16 in mixed fermentation medium which was about 16.35 mg/ml and lowest in jackfruit medium, 12.88 mg/ml at day 12. Whereas in the presence of Prescott salt, lowest citric acid production was also found in jackfruit medium, 7.21 mg/ml and highest in mixed medium, 11.54 mg/ml. In case of the previously isolated gamma-ray induced mutant *Aspergillus niger* 79/20, the yield seems to be higher under similar experimental condition.

**Keywords:** *aspergillus niger* 79/20, citric acid, titratable acidity.

Abstract: The worldwide demand for citric acid is increasing with the rising population and industrialization. The growing demand for citric acid and the need for alternative materials as substrates in the recent years have led to the choice of a novel and economically viable substrate, namely jackfruit (outer portion) and molasses for citric acid biosynthesis. Hydrolysis of these substrates with 0.05N HCl followed by fermentation using two isolates of Aspergillus niger were investigated for citric acid production under submerged culture condition in a period of 15 days. The products of the microbial metabolism namely residual sugar, total titratable acidity (TTA), citric acid, and biomass contents were determined periodically. Maximum citric acid production was found after 12 days of fermentation for both isolates, namely Aspergillus niger CA16, the parent strain and gamma ray induced mutant Aspergillus niger 79/20. Citric acid production was found highest in the absence of Prescott salt by Aspergillus niger CA16 in mixed fermentation medium which was about 16.35 mg/ml and lowest in jackfruit medium, 1.288 mg/ml at day 12. Whereas in the presence of Prescott salt, lowest citric acid production was also found in jackfruit medium, 7.21 mg/ml and highest in mixed medium, 11.54 mg/ml. In case of the previously isolated gamma-ray induced mutant Aspergillus niger 79/20, the yield seems to be higher under similar experimental condition. In absence of Prescott salt highest production of citric acid was found by mutant Aspergillus niger 79/20 in mixed fermentation medium which was about 22.12 mg/ml at day 12 which was even higher than that found in case of the parent strain Aspergillus niger CA16. In the presence of Prescott salt highest production of citric acid was found in mixed media, 16.35 mg/ml and lowest in jackfruit medium, 13.94 mg/ml which was again higher than that was obtained in case of the parent strain.

Keywords: aspergillus niger 79/20, citric acid, titratable acidity.

1. Introduction

Citric acid is one of the world’s largest tonnages of fermentation products. It is widely used in the food beverage industries as an acidifying and flavor-enhancing agent, pharmaceutical, chemical, cosmetic and other industries for applications such as acidulation, antioxidation, flavor enhancement, preservation, plasticizer and as a synergistic agent. The worldwide demand for citric acid is met by fermentation mainly by the process involving the filamentous fungus A. niger. A number of carbon sources may be used for citric acid fermentation. For commercial reasons, the uses of molasses, sucrose or glucose syrups are favored. The use of molasses in particular is desirable because of its low cost availability.

A. niger is capable of producing very high levels of citric acid, about 90% of the theoretical yield from a carbohydrate source. For an efficient citric acid production, the growth of Aspergillus in pellet form is desirable and this can be achieved by process optimization. There is a great worldwide demand for citric acid consumption due to its low toxicity compared with other acidulants used mainly in the pharmaceutical and food industries. Global production of citric acid has now reached 1.4 million tones and there is annual growth of 3.5–4.0 % in demand/consumption. A high rate of acidogenesis in A. niger is observed only under conditions of high glycolytic metabolism and can be induced by the addition of an excess amount of sucrose or other carbohydrates which induce a high rate of glycolytic catabolism. In this production technique, which is still the major industrial route to citric acid used today, cultures of Aspergillus niger are fed on a sucrose or glucose-containing medium to produce citric acid. The source of sugar is corn steep liquor, molasses, hydrolyzed corn starch or other inexpensive sugary solutions. Bangladesh, at present, imported cent percent citric acid from foreign countries. High production depends to a great extent on the strain used and its response to the composition of the medium can show a great deal of variability. Industrial production of this chemical by fermentation using cheap raw materials is helpful in economic development of our country. Keeping in view the future requirements and also the availability of cheap raw material, efforts were made to develop the process for citric acid fermentation, based on our local resources such as molasses from sugar mills and outer portion of jackfruit. So the purpose of the present study describes the feasibility of using raw and cheap materials such as molasses and outer portion of jackfruit for citric acid fermentation and to use parent strain CA16 & gamma-ray induced mutants for high citric acid yielding strain 79/20 of Aspergillus niger.
Aspergillus niger is a haploid filamentous fungi and is a very essential microorganism in the field of biology. A. niger is cultured for the industrial production of many substances. Various strains of A. niger are used in the industrial preparation of citric acid (E330) and gluconic acid (E574) and have been assessed as acceptable for daily intake by the World Health Organization. A. niger is important because of its involvement in producing citric acid as well as industrial enzymes, such as amyloses, proteases, and lipases. The uses of these enzymes are essential because of its importance for transformation to food enzymes. For example, A. niger glucoamylase is used in the production of high fructose corn syrup, and pectinases are used in cider and wine clarification. Glucose oxidase is used in the design of glucose biosensors, due to its high affinity for β-D-glucose. A variety of carbohydrate sources such as beet molasses, cane molasses, sucrose, commercial glucose, starch hydrolysates etc., have been used for citric acid production. Among these, sucrose, cane, and beet molasses have been found to be the best choice (Kapoor et al., 1982).

II. Materials and Methods

This study was done in the research laboratory of the Department of Biochemistry and Molecular Miology at Jahangirnagar University and at Institute of Food and Radiation Biology, Atomic Energy Research Establishment, Bangladesh during July 2009 and June 2010.

Parent strain Aspergillus niger CA16 and mutant strain Aspergillus niger 79/20 were first grown on agar slant medium. Each of the properly processed substrates [Molasses, jackfruit (outer potion) and mixed substrates] was hydrolyzed by 0.05 N HCl and filtered which were then used as medium for submerged fermentation. Each substrate were divided into two groups and were fermented separately, one in the presence of Prescott salt and the other in the absence. Each of the groups of the three types of media were further divided into another two subgroups and one of them was inoculated with the parent strain Aspergillus niger CA16 and the remaining one was inoculated with the mutant strain Aspergillus niger 79/20. All the flasks were then incubated for 15 days in an incubator under same conditions. Fermented media were collected on day 3, 6, 9, 12, 15 and were subjected to estimation of residual sugar, TTA value, citric acid concentration and pH determination.

III. Chemical Reagents and Solutions

All chemicals and reagents used in this study were of analytical grade. All aqueous solutions were prepared with distilled water. Stock solution of Prescott salt (NH4NO3: 2.23g/L, KH2PO4: 1.00g/L, MgSO4.7H2O: 0.23g/L) used in the media were prepared 10 times the media concentration and diluted as its normal strength in the experiment.

IV. Analytical Determination

At the different stages of fermentation the culture flasks were taken out of the incubator and the medium was collected onto the screw cap test tubes by pipetting and preserved at 0oC. The appropriate amount of sample was used for the estimation of total titratable acidity, citric acid and amount of residual sugar present in the medium after fermentation.

V. Determination of total Titratable Acidity (TTA)

Fermented medium (0.25ml) was diluted with 20ml of distilled water and was titrated against 0.1N NaOH solution using 2 to 3 drops of phenolphthalein as indicator. The value obtained was multiplied by 4 and total titratable acidity was expressed as ml of 0.1N NaOH required to neutralize 1ml fermented medium. The titrametric analysis of fermentation of each strain gave an indication of total acidity of the medium. The medium containing high TTA value i.e. higher acid content were then analyzed spectrophotometrically.

VI. Estimation of Citric Acid from Fermentation Medium

Citric acid was estimated spectrophotometrically by the reference method of Marier and Boulet (1958). Citric acid forms a color complex of polyvinyl keto-anhydridepolymer when it reacts with acetic anhydride and pyridine which can be estimated spectrophptometrically (Auterhoff and Schwingel, 1975). Following the growth of the organism aliquots of the medium were diluted so as to have concentration in the range of 25 to 200μg per ml (approximately) of citric acid.

VII. Estimation of Residual Sugar

Before inoculation and after completion of fermentation, samples were collected for initial and residual sugar estimation, respectively.

Following the fermentation, amount of residual sugar in the medium was determined by diluting the aliquots of the medium so as containing sugar concentration range of 25-200 μg per ml.

Initial and residual sugar of the medium was determined spectrophotometrically by anthrone method (Morse, 1947) using anthrone as the coloring agent with sucrose as standard.

VIII. Results

a) Estimation of residual sugar at different periods of citric acid fermentation

The residual sugar concentration was different in various media during citric acid fermentation by
Aspergillus niger parent strain CA16 and mutant strain 79/20. Prescott salt was also found to have an effect on sugar concentration during citric acid fermentation. In the presence of Prescott salt, residual sugar found in the molasses fermentation medium by Aspergillus niger CA16 on day 3, 6, 9, 12 and 15 was 34.81, 26.38, 21.13, 17.75 and 14.64 mg/ml respectively and that in the absence of Prescott salt residual sugar found was 35.19, 30.25, 23.75, 15.23 and 10.92 mg/ml respectively. Lowest amount of sugar was found at Day 15 on molasses fermentation medium by Aspergillus niger CA16 in the absence of Prescott salt (Figure-15). Residual sugar found in the molasses fermentation medium by Aspergillus niger 79/20 on day 3, 6, 9, 12 and 15 was 35.64, 29.62, 21.98, 16.20 and 11.51 mg/ml respectively, in the presence of Prescott salt and 40.12, 34.41, 30.13, 25.55 and 17.51 mg/ml respectively in the absence of Prescott salt. At Day 15 lowest amount of residual sugar was found on molasses fermentation medium by Aspergillus niger 79/20 in the presence of Prescott salt which is higher than that found by Aspergillus niger CA16 in the absence of Prescott salt (Figure-14 & 15).

When Aspergillus niger CA16 used jackfruit (outer portion) as fermentation medium, the residual sugar found on day 3, 6, 9, 12 and 15 in presence of Prescott salt was 30.34, 24.34, 20.04, 16.78 and 12.32 mg/ml respectively and in the absence of Prescott salt was 32.55, 27.79, 20.13, 13.24 and 8.40 mg/ml respectively. Lowest amount of residual sugar was found in the absence of Prescott salt on the day 15 on the jackfruit (outer portion) fermentation medium by Aspergillus niger CA16 (Figure-15). In presence of Prescott salt, concentration of residual sugar on jackfruit (outer portion) fermentation medium by the mutant fungus Aspergillus niger 79/20 was 32.69, 28.43, 23.12, 19.24 and 14.34 mg/ml on day 3, 6, 9, 12 and 15 respectively. On the other hand, the residual sugar concentration was 36.73, 30.29, 26.51, 20.91 and 15.12 mg/ml during same incubation periods in the absence of Prescott salt. Lowest amount of residual sugar was found in the presence of Prescott salt on the day 15 in the jackfruit fermentation medium by Aspergillus niger 79/20 which is higher than that found by Aspergillus niger CA16 in the absence of Prescott salt (Figure-14 & 15).

On the mixed fermentation medium, residual sugar found in presence of Prescott salt was 36.14, 30.47, 22.81, 19.33 and 15.94 mg/ml respectively and in the absence of Prescott salt was 40.23, 33.021, 25.17, 16.35 and 12.13 mg/ml respectively on day 3, 6, 9, 12 and 15 by Aspergillus niger CA16. Lowest amount of residual sugar was found in the absence of Prescott salt on day 15 in mixed fermentation medium by Aspergillus niger CA16. Lowest amount of residual sugar concentration was 38.81, 33.32, 29.62, 21.64 and 18.29 mg/ml respectively in mixed fermentation medium by Aspergillus niger 79/20 on day 3, 6, 9, 12 and 15. On the other hand, the residual sugar concentration in the absence of Prescott salt was 46.64, 41.69, 35.46, 29.60 and 20.12 mg/ml respectively on the same respective days. Lowest amount of residual sugar was found in the presence of Prescott salt on the day 15 in the jackfruit fermentation medium by Aspergillus niger 79/20 which is higher than that found by Aspergillus niger CA16 in the absence of Prescott salt (Figure-14 & 15).

Figure 14: Amount of Residual Sugar at different days of fermentation in various substrate (with Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20.

Figure 15: Amount of residual sugar at different days of fermentation in various substrates (Without Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20.

Figure 16: Amount of residual sugar at day 12 of fermentation in different substrates (with and without Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20. Here, P & A indicates presence & absence of Prescott salt respectively.
On day 12, the residual sugar found on each of the three types fermentation media by the parent strain *Aspergillus niger* CA16 were somewhat lower in the absence of Prescott salt. On the other hand the residual sugar found on the same types of media by the mutant strain *Aspergillus niger* 79/20 were comparatively lower in the presence of Prescott salt on day 12 (Figure- 16).

b) Estimation of TTA values at different period of citric acid fermentation

Total titratable acidity (TTA) of different fermented media were determined after different incubation periods during citric acid fermentation by *Aspergillus niger* parent strain CA16 and mutant strain 79/20. In each case the TTA values were found to increase gradually with the increase in incubation periods from day 3 and picked on day 12 and then started to decrease (day 15) [(Figure-17, 18 & 19) and (Appendix-II & V)].

On the molasses fermentation medium, TTA value obtained in the presence of Prescott salt by *Aspergillus niger* CA16 on day 3, 6, 9, 12 and 15 was 0.2, 0.5, 1.2, 1.5 and 1.3 respectively and that in the absence of Prescott TTA value found was 0.3, 0.96, 1.5, 2.68 and 2.16 respectively. Highest TTA value was found at Day 12 on jackfruit fermentation medium by *Aspergillus niger* CA16 in the absence of Prescott salt. When *Aspergillus niger* 79/20 was the strain used for fermentation on jackfruit medium, the TTA value found in the presence of Prescott salt on day 3, 6, 9, 12 and 15 was 0.8, 1.2, 2.1, 2.9 and 2.5 respectively and in the absence of Prescott salt was 1.0, 2.1, 3.2, 4.6 and 4.22. TTA value was highest at day 12 in the absence of Prescott salt for *Aspergillus niger* 79/20 which was higher than that obtained for *Aspergillus niger* CA16 (Figure-17 & 18).

In the presence of Prescott salt, TTA value found in the jackfruit (outer portion) fermentation medium by *Aspergillus niger* CA16 on day 3, 6, 9, 12 and 15 was 0.2, 0.5, 1.2, 1.5 and 1.3 respectively and that in the absence of Prescott TTA value found was 0.3, 0.96, 1.5, 2.68 and 2.16 respectively. Highest TTA value was found at Day 12 on jackfruit fermentation medium by *Aspergillus niger* CA16 in the absence of Prescott salt. When *Aspergillus niger* 79/20 was the strain used for fermentation on jackfruit medium, the TTA value found in the presence of Prescott salt on day 3, 6, 9, 12 and 15 was 0.8, 1.2, 2.1, 2.9 and 2.5 respectively and in the absence of Prescott salt was 1.0, 2.1, 3.2, 4.6 and 4.22. TTA value was highest at day 12 in the absence of Prescott salt for *Aspergillus niger* 79/20 which was higher than that obtained for *Aspergillus niger* CA16 (Figure-17 & 18).

TTA value obtained on day 3, 6, 9, 12 and 15 was 0.3, 0.95, 1.6, 2.4 and 1.67 respectively in the presence of Prescott salt and in the absence of Prescott salt was 0.5, 1.2, 2.8, 3.4 and 2.85 respectively when the parent strain *Aspergillus niger* CA16 was allowed to ferment the mixed medium. Highest TTA value found in the absence of Prescott salt for *Aspergillus niger* CA16 grown on mixed fermentation medium. When the same medium was fermented by *Aspergillus niger* 79/20, the TTA value obtained in the presence of Prescott salt on day 3, 6, 9, 12 and 15 was 1.0, 1.89, 2.9, 3.4 and 2.95 respectively and in the absence of Prescott salt the TTA value was 1.2, 2.7, 3.95, 5.38 and 4.89 respectively. Once again the highest TTA value was obtained for *Aspergillus niger* 79/20 on day 12 in the absence of Prescott salt which was higher than that obtained in case of *Aspergillus niger* CA16 (Figure-17 & 18).
Optimization of Citric Acid Production by Substrate Selection using Gamma Ray Induced Mutant Strain of Aspergillus niger

Citric acid concentration obtained on day 3, 6, 9, 12 and 15 was 1.44, 3.13, 6.73, 9.62 and 7.26 mg/ml respectively in the presence of Prescott salt and in the absence of Prescott salt was 1.92, 3.85, 8.65, 14.33 and 11.29 mg/ml respectively when the parent strain Aspergillus niger CA16 was allowed to ferment the molasses medium. Highest citric acid concentration found at day 12 in the absence of Prescott salt for Aspergillus niger CA16 grown on molasses fermentation medium. When the same medium was fermented by Aspergillus niger 79/20, the citric acid concentration obtained in the presence of Prescott salt on day 3, 6, 9, 12 and 15 was 3.85, 6.25, 11.54, 14.90 and 12.98 mg/ml respectively and in the absence of Prescott salt the citric acid concentration was 5.29, 11.54, 16.83, 23.56 and 20.67 mg/ml respectively. Once again the highest citric acid concentration was obtained for Aspergillus niger 79/20 on day 12 in the absence of Prescott salt which was higher than that obtained in case of Aspergillus niger CA16 (Figure-20 & 21).

These results showed TTA value was comparatively higher in the absence of Prescott salt for all the three types of media and for each of the strain. Throughout the incubation period the TTA value was highest in case mixed fermentation medium followed by molasses and jackfruit fermentation medium. Again, fermentation by Aspergillus niger 79/20 resulted in a comparatively higher TTA value than by Aspergillus niger CA16 both in the presence and absence of Prescott salt (Figure 19).

c) Estimation of citric acid accumulation at different period of citric acid fermentation

Accumulation of citric acid at different incubation periods on different media followed a very similar pattern as was seen in case of TTA value. Citric acid concentration was also different on different incubation periods with various fermentation media by the parent strain Aspergillus niger CA16 strain and the mutant strain 79/20. Citric acid concentration was found to increase gradually with the increase of incubation period and maximum citric acid concentration was found on day 12 in case of each of the three media. Finally, citric acid concentration was found to decrease at day 15 [(Figure-20, 21 & 22) and (Appendix-III & VI)].

On the jackfruit (outer portion) fermentation medium, citric acid concentration obtained in the presence of Prescott salt by Aspergillus niger CA16 on day 3, 6, 9, 12 and 15 was 0.96, 2.4, 5.77, 7.21 and 6.25 mg/ml respectively and in the absence of Prescott salt was 1.44, 4.62, 7.21, 12.88 and 10.38 mg/ml respectively. Highest citric acid concentration for Aspergillus niger CA16 was found in the absence of Prescott salt on 12 day. Citric acid concentration for mutant strain Aspergillus niger 79/20 on the same medium and on the same incubation periods was 3.85, 5.77, 10.09, 13.94 and 12.02 mg/ml respectively in the presence of Prescott salt and 4.29, 10.09, 15.38, 22.12 and 20.29 mg/ml respectively in the absence of Prescott salt. The highest citric acid concentration was obtained in the absence of Prescott salt for the mutant strain Aspergillus niger 79/20 which was higher than that found in case of parent strain Aspergillus niger CA16 (Figure-20 & 21).

Figure 19: Total Titratable Acidity at day 12 of fermentation in different substrates (with and without Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20. Here, P & A indicates presence & absence of Prescott salt respectively.

Figure 20: Citric acid accumulation at different days of fermentation in different substrates (with Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20.

Figure 21. Citric acid accumulation at different days of fermentation in different substrates (without Prescott salt) by A. niger CA16 and mutant strain A. niger 79/20.
In the presence of Prescott salt, citric acid concentration found in the mixed fermentation medium by Aspergillus niger CA16 on day 3, 6, 9, 12 and 15 was 1.44, 4.57, 7.69, 11.54 and 8.03 mg/ml respectively and that in the absence of Prescott citric acid concentration found was 2.40, 5.77, 13.46, 16.35 and 13.70 mg/ml respectively. Highest citric acid concentration was found at Day 12 on mixed fermentation medium by Aspergillus niger CA16 in the absence of Prescott salt. When Aspergillus niger 79/20 was the strain used for fermentation on mixed medium, the citric acid concentration found in the presence of Prescott salt on day 3, 6, 9, 12 and 15 was 4.29, 9.09, 13.94, 16.35 and 14.18 mg/ml respectively and in the absence of Prescott salt was 5.77, 12.98, 18.99, 25.87 and 23.51. Citric acid concentration was highest at day 12 in the absence of Prescott salt for Aspergillus niger 79/20 which was higher than that obtained for Aspergillus niger CA16 (Figure-20 & 21).

Throughout the incubation period the citric acid concentration was highest at day 12 in the absence of Prescott salt for A. niger CA16 and mutant strain A. niger 79/20. Here, P & A indicates presence & absence of Prescott salt respectively.

These results showed citric acid concentration was comparatively higher in the absence of Prescott salt for all the three types of media and for each of the strain. The fermentation medium followed by molasses and jackfruit fermentation medium. Again, fermentation by Aspergillus niger 79/20 resulted in a comparatively higher citric acid accumulation than by Aspergillus niger CA16 both in the presence and absence of Prescott salt (Figure-22).

Fermentation of citric acid for commercial production is dependent on many factors like quality of strains, nutritional composition of the media, environmental conditions, deficiency of manganese and other metals, pH, temperature and dissolved oxygen tension (Moyer, A. J. 1953). Usually, Aspergillus niger gives the best yield at around 25-28ºC. Increase in incubation period resulted in the increased citric acid production. A lower concentration of sugar leads to lower yield of citric acid as well as accumulation of oxalic acid (Kovats, 1960). But the use of wild type strain of Aspergillus niger is not cost effective. So, high yielding strains were searched which will give the best yield at around the room temperature. The superior strains Aspergillus niger CA16 and gamma ray induced mutants Aspergillus niger 79/20 seem to have fulfilled the requirement. Thus these strains can be conveniently exploited for the production of citric acid from cane molasses, jackfruit (outer portion) and a mixture of the two substrates.

From the findings of this study it is clearly suggested that both fermentation medium and Prescott salt have a considerable effect on the production of citric acid. Among the media used in this study, the mixed fermentation medium was found to be most suitable for citric acid production followed by molasses and jackfruit (outer portion) media. Another important finding of the present study was that Prescott salt was found to have a negative effect on the citric acid production by the either strains of Aspergillus niger. Again the gamma-ray induced mutant strain, Aspergillus niger 79/20 had a yield efficiency more than that of the parent strain Aspergillus niger CA16 and thus considered superior to the parent strain Aspergillus niger CA16. Thus as far as citric acid production is concerned the mixed medium in the absence of Prescott salt is the most suitable medium and the gamma ray induced mutant strain Aspergillus niger 79/20 is the preferred organism.
