Makerere University School of Public Health

Abstract - Background: Adjumani District in Uganda has hosted refugees in camps since the onset of the South Sudan conflict in Dec 2013. Since then, Adjumani refugee settlements have experienced measles, cholera, and hepatitis E outbreaks. Health care, disease surveillance, and response for these refugees is carried out by both government health facilities and nongovernmental organizations (NGOs) using the Integrated Disease Surveillance and Response (IDSR) guidelines.

Methods: We evaluated attributes of the surveillance system using CDC MMWR 2001 guidelines for public health surveillance as a reference. Time lininess was defined as proportion of reports received by the monthly due dates at the MOH. We interviewed District Health Team and health facility staff using a standardized questionnaire to determine their readiness to conduct IDSR, and used a checklist to ascertain the availability of surveillance tools.

Results: The surveillance system was adequate regarding stability, acceptability, and representativeness. NGO health facilities used HIS, which lacked some variables in the standard HMIS used by the MOH.

Keywords: surveillance system evaluation, refugee setting, uganda.

Abstract: Background: Adjumani District in Uganda has hosted refugees in camps since the onset of the South Sudan conflict in Dec 2013. Since then, Adjumani refugee settlements have experienced measles, cholera, and hepatitis E outbreaks. Health care, disease surveillance, and response for these refugees is carried out by both government health facilities and nongovernmental organizations (NGOs) using the Integrated Disease Surveillance and Response (IDSR) guidelines.

Methods: We evaluated attributes of the surveillance system using CDC MMWR 2001 guidelines for public health surveillance as a reference. Time liness was defined as proportion of reports received by the monthly due dates at the MOH. We interviewed District Health Team and health facility staff using a standardized questionnaire to determine their readiness to conduct IDSR, and used a checklist to ascertain the availability of surveillance tools.

Results: The surveillance system was adequate regarding stability, acceptability, and representativeness. NGO health facilities used HIS, which lacked some variables in the standard HMIS used by the MOH. We found poor timeliness [56%] and reporting rates [63%] across all diseases. The District Rapid Response Team [DRRT] and Epidemic Preparedness and Response Committee functioned only in confirmed outbreaks, and had no planning and review meetings.

Conclusions: The surveillance and response exist in Adjumani District but do not operate optimally. There was lack of harmonization between NGO surveillance activities and government health facility surveillance activities. We recommended harmonization of the HIS and HMIS reporting system in the district, and provision of appropriate recording and reporting tools by the District Health Officer.

Keywords: surveillance system evaluation, refugee setting, uganda.

I. BACKGROUND

Populations affected by armed conflict, many in Africa such as South Sudan, Democratic Republic of Congo (DRC), Burundi, and Somalia have been heavily affected by conflict in recent years, leading to massive movement of refugees and internally-displaced persons [2]. Refugees and internally-displaced persons often experience elevated mortality rates during the period immediately following their migration, due to increased rates of diarrheal diseases, measles, acute respiratory infections, and malaria. High prevalence of acute malnutrition, especially amongst children, has compounded the problem further [3].

The conflict in South Sudan has resulted in massive displacement of its citizens to neighbouring countries. Uganda, South Sudan’s neighbour to the south, has received over 640,000 refugees since the onset of the conflict in December 2013; this number has recently compounded due to renewed conflict and hostilities that began in July 2016. Presently, there are approximately 200,000 refugees, both Sudanese and Congolese, in Adjumani district in Uganda. The West Nile region of Uganda, which includes Adjumani district, experiences annual epidemics of cholera, meningococcal meningitis, plague, measles, and hepatitis E. These epidemics often have high case-fatality rates (CFRs) [2]. The hosting of Sudanese and Congolese refugees in this region has increased the risk for epidemics because of the poor living conditions in the camps and settlements.

The Adjumani Refugee Settlements were some of the first to receive and resettle refugees since the onset of the Sudanese conflict in December 2013. Currently, approximately half of Adjumani district’s population of ~430,000 comprises refugees. This has increased the vulnerability of Adjumani district to both disease outbreaks and to seasonal peaks in malnutrition. Since the start of the emergency in South Sudan, refugees in the Adjumani settlements have experienced a measles outbreak in January 2014, cholera outbreaks in August 2015 and August 2016, and cases of hepatitis B. There is also high morbidity from childhood illnesses, particularly malaria, upper respiratory tract infections, and watery diarrhea, partially related to overcrowding in the camps[6]. These tend to peak during rainy seasons due to inadequate household hygiene and sanitation practices and poor or no vector control mechanisms.

Author y: Ministry of Health, Kampala, Uganda.
The Integrated Disease Surveillance and Response (IDSR), developed by WHO/AFRO in 1998 and adopted by Uganda in 2000, is the national strategy for conducting and improving epidemiologic surveillance and response in Uganda, including in refugee settlements. In 2001, Uganda developed National IDSR Technical Guidelines, with emphases on epidemic-prone diseases, diseases targeted for elimination and eradication, diseases of public health importance [19]. Epidemic Prevention and Preparedness Response (EPPR) is part of the Uganda National Minimum Health Care Package [1]. EPPR in Uganda is a mandate of the Ministry of Health (MoH) as well as district governments. Epidemic-prone diseases in Uganda include cholera, bacillary dysentery, plague, meningococcal meningitis, viral hemorrhagic fevers (Ebola and Marburg), malaria, typhoid and hepatitis E [8]. Health care, disease surveillance, and response for refugees is carried out by both government health facilities and NGOs. In the data collection for IDSR, Ministry of health uses the Health Management and Information system tools (HMIS) i.e. registers, forms, case investigation forms. The HMIS system ideally was supposed to replace the Health Information system (HIS) which is used by many NGO agencies.

Every surveillance system should be evaluated periodically with recommendations to improve its usefulness, quality, and effectiveness [8, 9]. We evaluated the public health surveillance system to determine Adjumani District’s preparedness to implement IDSR [8].

II. METHODS

Study Settings: Adjumani District has 17 resettlement camps for refugees, who are mainly from South Sudan and the DRC. The total refugee population for Adjumani District stood at 209, 048 in 2017 [4]. The settlement areas are organised in clusters, blocks, and zones. A zone is the largest unit, which comprises 3 to 6 clusters. Clusters are smaller organisational units within the zones comprising groups of households. The households within the clusters are organised in blocks [4].

Study Design: We conducted a descriptive study to determine the readiness of Adjumani District Health Teams [DHTs] to conduct IDSR in April 2017. We evaluated the IDSR system serving the settlements using United States Centers for Disease Control [US CDC] guidelines for evaluation of public health surveillance systems. Eight health facilities [i.e. Adjumani hospital, Mungula HCIV, Lewa HCII, Pagirinya HCIII, Ayilo HCIII, Biira HCIII, Ayilo HCII, Pagirinya HCII] serving the five refugee settlements were considered for the evaluation. We assessed all health facilities for the recommended Ministry of Health staffing norms (i.e. for health center III, 2 clinical officers, 2 midwives, 3 nurses, 2 laboratory staffs, one health assistant, one records assistant; for health center II, one midwife, two nurses, one health assistant).

Data Collection: We conducted face-to-face interviews using a semi-structured questionnaire with the health facility [HF] in-charges and surveillance focal persons to collect information regarding the surveillance system attributes. We conducted focus group discussions with the District Epidemic Preparedness and Response Committee (DEPRC) and the District Rapid Response Team [DRRT] to obtain information on their functionality. We also held a consultative meeting with Village Health Teams (VHTs) and their focal persons to collect information on community surveillance.

Attributes of the Surveillance System Evaluated: We first developed a surveillance system description, including describing what the system was designed to accomplish, who the stakeholders were, system flow, data use, case definitions, detection algorithms, privacy/confidentiality, and communication of data. Next, we assessed multiple attributes, including those below, and made conclusions and recommendations for use and improvement of the syndromic surveillance system.

Usefulness: ways the system had demonstrated value relevant to public health Acceptability: stakeholders’ willingness to contribute to and use the system. Generalizability: how readily the system could be duplicated in another location Stability: the reliability (i.e., the ability to collect, manage, and provide data properly without failure) and consistent availability (the ability to be operational when needed) of the public health surveillance system. Flexibility: How adaptable the system was to changing needs and risk thresholds. Sensitivity: the proportion of cases and outbreaks detected by the system that were true cases and outbreaks, and proportion of alarms triggered by the system that are true alarms (true positives). Timeliness: reporting was assessed as timely if the reports were within the Ministry of Health recommended timelines and late if otherwise. Representativeness: how well the system reflected the population of interest. Completeness: proportion of data that were present for each record. Reliability: measure of how well the data captured were consistently across the system and over time.

Ethical Consideration: The Ministry of Health of Uganda through the office of the Director General Health Services gave the approval to conduct this investigation. Additionally, the office of the Associate Director for Science, US Centers for Disease Control and Prevention, Uganda, determined that this investigation was not human subjects’ research because the primary purpose was to identify, characterise, and control disease in response to a perceived immediate public
health threat. Permission was also received from the
Adjumani District Health Officer. The qualitative
interviews were only conducted after written informed
consent was given to the participant.

III. Results

a) Description of the Surveillance System

Adjumani District government health facilities
currently use the IDSR system to report epidemic-prone
diseases [11]. Due to unavailability of reliable power in
many peripheral facilities, the paper-based system is
used in these facilities, while the electronic system is
used from the district office upwards. In brief, healthcare
workers at government health facilities identify
suspected cases of epidemic-prone diseases and fill in
standardized paper HMIS paper case report forms for
the appropriate disease. The forms are dispatched
manually to the District Health Office, where the District
Biostatistician enters and analyzes the data inDHIS2
(District Health Information Software2) and then submits
it back to the district. The MoH summarizes these data on a monthly
and quarterly basis.

On a weekly basis, health facilities also use a
system called Mtrac (Mobile tracking of Health
Services), which involves the use of toll-free cellphones
to relay information on epidemic-prone diseases as well
as medicine stock balances to the district health office,
where the data are cleaned, validated, and approved
before submission to MoH. These data are integrated
into the monthly report from the District to the MoH. The
ministry gives feedback to through assessment of the
performance indicators as per the sent reports.

Of the eight sites supporting the refugee camps
in Adjumani District, four are supported by the Ugandan
government and four by NGO implementing partners.
The implementing partner-supported sites have another
parallel system of reporting, whereby the facilities use a
largely paper-based system with HIS (Health Information
System, different from HMIS) forms to collect
information. These data are relayed from the facilities to
the NGO implementing partners, which also have a
biostatistician to aggregate and analyze data, and relay
it back to the district.

b) Information Flow

At all the health facilities visited respondents
were conversant with the flow of information, however;
the reporting system was adhered to by the
government-supported facilities only. Reporting tools
used by the NGO-run facilities were different from the
tools used by the government facilities (HIS vs HMIS),
and NGO-run facilities were not reporting to the Uganda
MoH system. Most of the reporting was to United
Nations High Commissioner for Refugees (UNHCR). All
the health workers interviewed reported lack of feedback
from their superiors about the submitted reports.

The District Epidemic Prevention Preparedness
and Response Committees (DEPPRC) or disaster
committees were present in Adjumani district, though
found to be only functional during times of outbreaks
and disasters. Ideally, these committees are supposed to
sit on a quarterly basis to review their epidemic
preparedness plans.

Of the 8 health facilities visited, 5 (63%)
adhered poorly to the IDSR-recommended systems for
surveillance. No health facility displayed information on
priority diseases. All health facilities were ill-prepared to
handle emerging epidemics. There were no supplies
appropriate for an emerging epidemic, such as personal
protective equipment or disinfectants, and none of the
facilities could estimate supplies for emergencies.
Feedback mechanisms on the submitted reports and
samples sent to the national laboratories were found to
be very poor from the district and national level; many of
the health facilities serving refugee populations reported
having sent suspected laboratory samples to the district
and MoH without receiving feedback on results.

c) Laboratory Infrastructure

We found that the laboratory infrastructures at
the periphery of the district serving the camps
compromised regular and outbreak surveillance functions
due to inability to diagnose epidemic-prone
diseases. Suspected cholera and measles samples had
to be transported to the district, then to the regional
deferral hospital for diagnosis, while samples from
patients with suspected rubella and viral hemorrhagic
fevers needed to be transported to the Uganda Virus
Research institute, far from the site. There were no
specimen/sample collecting bottles in any laboratories;
laboratories were improvising with used intravenous
drug bottles. Many HCII facilities were the first contact
for diagnostics in refugee settlement areas, and none of
them had a laboratory facility (as per the MoH policy).
Only the district hospital could confirm some of the
priority diseases. Health Centre IIIs and IVs had
laboratories, although their capacities were limited.
Sample collection for HIV treatment monitoring (viral
load, CD4, Renal and Liver function tests) and
transportation was good and this was complemented by
the national sample transportation system (hub system).

d) Attributes of the IDSR system for Adjumani District
Surveillance System Resource Requirements: The
surveillance system had no separate budgetary
allocation for its operation. Prioritization of the
surveillance activities in the district and facility work
plans was lacking in all facilities. All the health facilities
had an accessible means of transport to deliver
specimens and suspected patients to the district
hospital. However, there were no specimen/ sample
collection containers in any facilities except Adjumani
Hospital.
Usefulness of the Surveillance System: The surveillance system in Adjumani was found to be sub-optimally functional in terms of data use. Data were used to make decisions only during epidemics. These data were not used to make realistic estimations of resource requirements for prevention and containment of an epidemic for or for program planning, nor to calculate baseline levels of disease.

Human Resource Capacity: All health facilities selected had designated surveillance and HMIS staff. Non-governmental organization-supported facilities were overstaffed, according to MoH staffing norms.

Timeliness: The reporting rates for most health facilities were poor with government facilities (i.e., Adjumani hospital, Mungula HCIV, Biira HCIII, Lewa HCII) having late reporting and most NGO facilities were not reporting at all (Table 4).

Simplicity: The system was found to be complex in structure as evidenced by special or follow-up laboratory tests to confirm the case; investigation of the case, including telephone contact or a home visit by public health personnel to collect detailed information; multiple levels of reporting (e.g., with the National Notifiable Diseases Surveillance System, case reports might start with the health-care provider who makes the diagnosis and pass through county and state health departments before going to CDC [29]); and integration of related systems whereby special training is required to collect and/or interpret data. Many health workers were not even aware of the standard case definitions. Data flow wasn’t systematic (i.e. from health center to health sub district then to district as recommended by MoH). The case investigation forms were not readily available at the health facilities, and one had to consult the DHOs office in case of a suspected epidemic-prone condition for verification by the district surveillance focal point person. This was more evident among the non-government health facilities; health workers from some of these facilities had never seen case investigation forms. There were multiple levels of reporting of suspected events, with the NGO-supported sites having the HIS system as opposed to the HMIS recommended by the Uganda MoH, and reporting to their agencies before reporting to MoH.

Flexibility: Flexibility was evaluated retrospectively by observing how a system had responded to a new demand. There were revised case definitions, additional data sources, new information technology, and challenges in funding. The system had failed to integrate the HIS with the recommended HMIS, which offered immense challenges to the service providers, primarily in the partner-supported sites when some information required by HMIS was not captured by the HIS tools. All NGOs are supposed to report through the MoH structure; however, the HIS tools didn’t capture some of the required MoH variables.

Acceptability: The NGO-supported health facilities had a parallel structure for reporting through the HIS. This allowed them to bypass the MoH reporting system and report to their donors. Data flow wasn’t through the MoH. Most of these facilities did not report through the HMIS system, and those that did were either late or incomplete.

Sensitivity: The system was found to be sensitive because it was able to detect epidemic prone diseases or other health-related events that were occurring in the population under surveillance. Since the start of the emergency in South Sudan, refugees in the Adjumani settlements have experienced a measles outbreak in January 2014, cholera outbreaks in August 2015 and August 2016, and cases of hepatitis B. The system was able to detect and report all these outbreaks.

Data Quality: The quality of data was poor. Specifically, there were many missing variables leading to incomplete data. The registers in some of the NGO health facilities were lacking standard reporting tools and were using different tools for data collection with most required variables not captured.

Stability: The system was found to be unstable primarily because most health facilities were using a manual system to generate and store data (i.e., paper-based). Tracing reports in most health facilities was difficult. There were no funds for surveillance activities in all the health facilities, with funds only being availed after outbreaks are confirmed.

Representativeness and Completeness: Four out of the eight health facilities assessed consistently reported in their monthly and weekly reports on the reportable diseases. In four health facilities, weekly reports were missing.

Data Analysis: Data were neither analysed at the health facility nor the district level.

IV. DISCUSSION

The surveillance system in the refugee settlements of Adjumani District faced many challenges, which likely compromised its effectiveness. We found the surveillance system to be lacking in all the attributes assessed except sensitivity, as there was evidence that it was achieving one of the key surveillance objectives of detection and prevention of epidemics. Evaluation of the surveillance system was designed to help policymakers in the given country to set priorities for future planning, resource allocation, and future interventions to help prevent disease [12, 13]; however, the challenges faced by the system in its current state will make that difficult.

Although DEPPR and DRRT structures existed in the district, they only met during outbreaks and times of disaster. Similar findings were found in a study in West Nile where many district committees didn’t convene meetings regularly [14]. The reasons for the
noncompliance in our study was due to the underfunding by the district to carry out surveillance activities and lack of prioritization.

Most health facilities were not using the IDSR tools, and reporting rates for Adjumani were below the national target of 80%. Non-governmental health facilities mainly serving the refugee settlements did not report to the MoH [11]. This could be partially explained by the fact that there is a parallel system of reporting for United Nations High Commission for Refugees (UNHCR)/Medical Teams International (MTI)-supported units with the health care workers using HIS (as opposed to the HMIS reporting system from MoH), and that the facilities did not want to double-report [15]. However, NGO-supported health facilities’ failure to report affected the general reporting rates for the district and surveillance as a whole, as it compromised the ability to detect outbreaks in the district. The NGO-supported health facilities also lacked the standard MoH tools such as the case investigation tools and registers.

Although an electronic system was implemented in 2012 the reporting systems were primarily paper-based, with only a few facilities having access to the electronic system. This was due to irregular power supply in the remote settlements. This failure to be able to use an electronic system affected reporting timeliness, and, in the long run, timely detection of outbreaks. Most health facilities serving the resettlement areas were overstaffed with highly qualified staffs according to the MoH staffing norms. However, these additional staff could be useful in assisting with surveillance.

Limitations: We were not allowed access to source data to evaluate the system through audits.

V. Conclusions

Generally, the structures for epidemic preparedness and prevention exist in Adjumani District but are operating sub-optimally. There was lack of harmony in the operations of NGO agencies and government health facilities in the performance of the surveillance function.

VI. Recommendations

We recommended harmonization of the HIS and HMIS reporting system in the district, and provision of appropriate recording and reporting tools by the District Health Officer. There is need to avail the case investigation tools, case definitions booklets and charts, standard tool to both governmental and non-governmental facilities. The DHO’s office should have a contingency plan in case of epidemics. Supportive supervision of health facilities should be stepped up to improve on upward reporting of HMIS data. The district laboratory should be supported to procure and stock transport media for proper collection and transport of clinical specimens during particular disease outbreaks.

Public Health Actions: Following the evaluation, we conducted IDSR training for 25 health workers serving the settlement area as a way of addressing some of the identified gaps. In collaboration with Adjumani DHT and Action Against Hunger (ACF), we developed the District Epidemic Preparedness and Response Plan.

Acknowledgment

I would like to thank the Ministry of Health Uganda, Public Health Fellowship programme, AFENET for all the support during the development of this manuscript.
