Study of Acute Toxicity of Phytopreparation Parodonfit

By Zhuraeva Aziza Alisherovna, S. A. Saidov & B.S. Tulyaganov

Tashkent State Dental Institute

Abstract- The object of the study is a liquid alcoholic extract under the code name "Parodonfit" - containing medicinal plants, such as Salvia officinalis, Matricariachamomilla, Calendula officinalis, Hypericumper foratum. The chemical composition of this phytocomposition was previously studied. Moreover, alkaloids, flavonoids, saponins and tannins were found in the composition of the liquid extract. Given the traditional use of this phytocomposition in dentistry, it is of undoubted interest to develop a dental dosage form based on it for the treatment of diseases of the oral mucosa. The article presents the results of a study of acute toxicity of the Parodonfit liquid extract.

Keywords: acute toxicity, parodonfit, liquid extract, dentistry, salvia officinalis, matricariachamomilla, calendula officinalis, hypericumperforatum.

Abstract- The object of the study is a liquid alcoholic extract under the code name "Parodonfit" - containing medicinal plants, such as Salvia officinalis, Matricaria chamomilla, Calendula officinalis, Hypericum perforatum. The chemical composition of this phytocomposition was previously studied. Moreover, alkaloids, flavonoids, saponins and tannins were found in the composition of the liquid extract. Given the traditional use of this phytocomposition in dentistry, it is of undoubted interest to develop a dental dosage form based on it for the treatment of diseases of the oral mucosa. The article presents the results of a study of acute toxicity of the Parodonfit liquid extract.

Keywords: acute toxicity, parodonfit, liquid extract, dentistry, salvia officinalis, matricaria chamomilla, calendula officinalis, hypericum perforatum.

I. Relevance

The availability of modern affordable drugs is the basis for the treatment and prevention of the vast majority of diseases of modern man and an indicator of the social and economic development of society. The creation and implementation of new highly effective medicines (PM) based on plant materials growing in the regions of Uzbekistan is a priority for experimental scientists, technologists, doctors and public health authorities of the Republic of Uzbekistan. The development of drugs for dental practice is a very relevant area, since infectious and inflammatory periodontal diseases are common among the general population. According to the WHO, infectious and inflammatory periodontal diseases are common among the general population. The increased interest in medicinal plants, especially in the last decade, was the result of more frequent allergic reactions and complications after the use of antibiotics, hormones and other drugs. In contrast, medicinal plants rarely cause unwanted adverse reactions from the body, are non-toxic and well tolerated by patients regardless of age. Medicinal herbal remedies have high therapeutic efficacy and minimal toxicity [1].

Purpose of the study: The aim of this work is to study the acute toxicity of the Parodonfit liquid extract.

II. Materials and Research Methods

The study of the acute toxicity of the test substance, with the Chlorophyllipt comparison drug, 1% alcohol solution in the first series of experiments was carried out according to the generally accepted method [1,2] on 42 white mice weighing 19-21 g of both sexes. The studied substance of the Parodonfit alcohol liquid extract in a ratio of 1:10 was administered to animals orally at a dose of 0.25; 0.5 and 0.75 ml per animal weight, which corresponds to 12.5 mg / kg, 25 mg / kg and 37.5 mg / kg. Control was animals that were orally injected with saline in an equivalent volume.

Observation of the condition of the animals was carried out in vivarium conditions for 14 days. In this case, the general condition and behavior of the animals was taken into account. With the introduction of the substance at a dose of 12.5 mg / kg-25 mg / kg, no changes were noted. Animals were active, took water and food, reacted to external stimuli. While the introduction of 37.5 mg / kg contributed to a marked limitation of mobility, respiration became superficial and rapid. The observed changes lasted for 30-40 minutes, then independently passed and the state of the animals returned to its original state. In this case, no pathological reactions in the behavior of animals were noted. They were active, there were no signs of intoxication and completely ate food. General behavior, coat color, mucous membranes, respiration, palpitations, locomotor activity, and death of mice were taken into account. The death of animals during the observation period (within 14 days) was not observed.

In the second series of experiments, in accordance with the methodological recommendations, acute toxicity was studied on Syrian sexually mature hamsters weighing 97-135 g by regularly treating the oral cavity of the Parodonfit liquid alcohol extract with a de-alcoholized evaporation method to 1/3 of the initial volume, followed by bringing water to the original amount 0.5-1.0 ml per animal. It is known that testing on Syrian hamsters is the most appropriate method for testing preclinical studies in dental practice [6]. To reproduce by irrigation, the studied alcoholic extract was introduced, which was prepared in advance in a de-alcoholized form on the mucous membrane of the buccal space in an amount of 0.5-1.0 ml per animal. Temperature was maintained in the range of 18-25 ° C, relative humidity - 30-70%. Acute toxicity was evaluated by changes in body weight and neuro-somatic indicators:

- General condition of the animal
- Behavior features
- The intensity and nature of motor activity
- The presence and nature of seizures
- Coordination of movement
- Reaction to tactile, pain, sound and light stimuli
- Frequency and depth of respiratory movements
- Condition of hair and skin

All manipulations with animals were carried out in accordance with the "International rules for working with laboratory animals" [4,5,7]. As a study of acute toxicity showed, the behavior of animals from the experimental group did not differ significantly from the control group. The condition of the coat and mucous membranes remained unchanged. During the experiment, no deaths were observed. Due to the above
parameters, there were no changes in laboratory animals.

IV. CONCLUSIONS

Thus, with a single oral administration, the Parodonfit liquid alcohol extract in terms of acute toxicity compared to Chlorophyllipt 1% alcohol solution belongs to the class IV of relatively harmless substances [3], as well as during the irrigation of the oral mucosa on mature Syrian hamsters, the alcohol extract under study can be considered harmless.
