5

A 30-year-old male with no significant past medical history developed a stroke on day 15th of his COVID-19 Positive result with investigations showing Thrombosis of Left ICA/MCA. The patient underwent mechanical thrombectomy with adequate recanalization yet presented with a recurrent thrombus the next day. Hypercoagulable state is one of the unusual complications seen in COVID-19 positive patients with multiple pieces of literature pointing towards increased risk of venous thromboembolism, with stress towards VTE prophylaxis[1,2]. Arterial thromboembolism is a lesser-known sequela, often involves larger blood vessels correlating

 $_{15}$ $\,$ with increased inflammatory markers and severity of the disease, and such patients may need

- ¹⁶ prolonged anticoagulation therapy.

Complication of Covid-19 Infection: A Case Report and Review of Literature Abstract-A 30-year-old male 20 with no significant past medical history developed a stroke on day 15th of his COVID-19 Positive result with 21 investigations showing Thrombosis of Left ICA/MCA. The patient underwent mechanical thrombectomy with 22 adequate recanalization yet presented with a recurrent thrombus the next day. Hypercoagulable state is one of 23 the unusual complications seen in COVID-19 positive patients with multiple pieces of literature pointing towards 24 increased risk of venous thromboembolism, with stress towards VTE prophylaxis [1,2]. Arterial thromboembolism 25 is a lesser-known sequela, often involves larger blood vessels correlating with increased inflammatory markers and 26 severity of the disease, and such patients may need prolonged anticoagulation therapy. 27

28 **2 I**.

Introduction/background n late December 2019, the first case of the novel coronavirus was first identified in 29 Wuhan, China, and on Mar 11, 2020, the WHO officially declared it a worldwide pandemic. Since then, the 30 world has faced many challenges to overcome and adapt. The novel Coronavirus can present in a spectrum 31 ranging from asymptomatic to the critically ill, with 81% exhibiting mild symptoms [3]. Its high infection rate 32 has left the medical world at unprecedented times with new aspects of the virus observed in each specialty and 33 requires a multidisciplinary approach to treat the many organs affected. Many studies point to the primary 34 pathogenesis in ARDS/Multiorgan failure in these patients is a Hypercoagulable/Prothrombotic state. We want 35 to present an otherwise healthy 30-year-old COVID-19 positive patient developing an Acute Stroke involving the 36 ICA/MCA. 37

38 **3 II.**

³⁹ 4 Case Presentation

40 A 30-year-old male with no known significant past medical history works as a construction worker presented to 41 the ED by complaining of a fever, dry cough, headache, and a sore throat. He has a history of contact with his $_{\tt 42}$ $\,$ roommate, who was also experiencing similar symptoms. He denied shortness of breath or chest pain and tested

positive for COVID-19 by real-time reverse Transcriptase-Polymerase Chain reaction Swap test (RT-PCR). The
 examination was unremarkable, a selective blood workup including CBC, CMP, CRP, and a G6PD screening, all

of which showed no significant abnormalities. An initial chest x-ray performed at admission was unremarkable,
and the patient transferred to the quarantine facility as per the CDC protocol.

On admission to the quarantine facility, repeat blood work was done, including an ECG and a repeat chest 47 x-ray, which showed patchy consolidation in the left lower lung zone. The patient has remained stable, and 48 without any complaints until the day 15th post positive COVID-19 PCR test, the patient collapsed and was 49 unresponsive initially with a GCS score of 11. Vital signs were measured, showing a blood pressure of 99/62 50 mmHg, Heart Rate of 107 bpm, Oxygen Saturation of 92%, Random Blood Sugar 100 mg/dL, and the patient 51 was afebrile. On examination, the patient showed right-sided facial palsy and hemiplegia with a power of the 52 right upper limb and right lower limb of 0/5 and 2/5, respectively, left upper and lower limbs were 5/5 with 53 intact sensation. The patient was immediately transferred to a specialized stroke unit by ambulance. 54

55 **5 III.**

56 6 Investigations

Upon arrival to the ED, vitals were as follows: BP 120 /72, HR 100, oxygen saturation 93 % on room air, and 57 picked up to 97% on 3 L nasal cannula, respiratory rate of 23, and afebrile. On examination, the patient was 58 confused with global aphasia and muteness, right hemianopia, right gaze deviation, right facial weakness, and 59 right hemiplegia (arm 0/5, leg 2/5). NIHSS score-22 and mRS -0. A repeated chest x-ray was done, noting air 60 space opacity in the middle and lower lung zones bilaterally (figure 4). His Labs showed WBC-7.8, HCT47.5, 61 INR1.1, Pt-12.5, APTT-25.9, CPR-58.7, Ferritin-619. Unfortunately, the D-Dimer sample was not sent to the 62 lab 63 Stroke protocol was activated, and an urgent CT scan along with a perfusion scan. A plain CT scan showed 64 65 subtle hyperdensity in the left MCA (Figure 1a) with no apparent intracerebral or subarachnoid I hemorrhage 66 with normal ventricles in position and size subarachnoid spaces looked unremarkable. CT perfusion revealed CBF 67 and CBV (Figure ??b and 1c) apparent mismatch in the left cerebral hemisphere, mainly in the left frontoparietal region in the left MCA territory with a delay in MTT/T max images, suggestive of tissue at risk. While in CT 68 angiogram, there was the small filling defect of in the left CCA in the neck proximal to the bifurcation, plus partial 69 filling defect left ECA in the neck along with narrowing of the lumen of the left CCA in petrous and cavernous 70 segments with no opacification in the supra-clinoid part of the left CCA and also non-visualized M1 segment of 71 the left MCA, suggestive of a partial block. In contrast, the right ACA/MCA and posterior circulation looked 72 unremarkable. The patient was admitted to the ICU in a monitored bed and continued to receive care according 73 to the stroke management protocol; he remained aphasic with right-sided hemiplegia. There were No arrhythmias 74 or ECG abnormalities. Follow up CT scan done 24 hours after the thrombectomy showed hyperdensity in the left 75 MCA, suggestive of recurrent thrombus. Repeat CT and CTA showed a significant interval increase in the extent 76 of vascular occlusion, involving the entirety of the left internal carotid artery beyond the bifurcation and the M2 77 78 and M3 segments of the left MCA (previously only in the M1). Redemonstrations of the small filling defect in 79 the left external carotid artery with no significant interval change. The right CCA, ICA, MCA, and both ACAs appear patent with no evidence of occlusion, and the vertebrobasilar system appears patent with no evidence of 80 occlusion as well (figure 3). A cardiac echo done to rule out any source of thrombo-emboli was unremarkable. 81 Serology work up for Lupus anticoagulant showed the first sample to be negative; however, the repeated sample 82 tested positive with negative anticardiolipin and negative Anti Glycoprotein. His Protein C, Protein S, and ATA 83 were normal. Connective Tissue disorder workup was done, with ANA, full ENA panel, which was healthy. 84

85 7 IV.

86 8 Differential Diagnosis

In this case, the primary etiology of stroke is COVID 19 related thrombo-inflammation leading to stroke or coagulopathy related to the virus, less likely cause is ischemic stroke as the patient is young without any comorbidities.

90 V.

91 9 Treatment

The patient was started on anticoagulation (enoxaparin and followed by warfarin) with an INR target of 2-3, with a plan to repeat DSA after four weeks of anticoagulation treatment. He was tested negative on two samples of the COVID-PCR swab test, taken 24 hours apart on day 25th, with repeat chest x-ray showed regression of the bilateral pulmonary consolidation and infiltration, and the patient is more alert and awake, started verbalizing but has slurred speech.

97 10 VI.

⁹⁸ 11 Outcome and Follow-up

⁹⁹ The patient is still undergoing treatment understroke and rehab unit, with an active rehab session, and is expected ¹⁰⁰ to be transferred to the rehabilitation unit.

101 **12 VII.**

102 **13** Discussion

Thromboinflammation or COVID-19-associated coagulopathy (CAC) [4], is a term coined for Hypercoagulable state in Covid-19, characterized by an elevation in procoagulant factor levels including fibrinogen, and an increase in D-dimers correlated with higher mortality. The occurrence of thromboembolic events in Covid-19 disease has been proven by Postmortem examination of COVID19 patients reveals diffuse alveolar damage with severe capillary congestion and variegated findings of lungs and other organs suggesting vascular dysfunction [5].

Oxley TJ et al. [6] presented 5 cases of Young adults (all aged between 33-40 years) who have developed 108 stroke due to large vessel involvement and tested Coivd-19 PCR positive. While our example is also a young 109 adult without any co-morbidities, it is interesting to note that his chest X-ray progressed to worse on the 110 day of the stroke and even the inflammatory markers were highest on the day of the stroke, raising a high 111 level of suspicion of association between COVID-19 related inflammation and stroke (Figure 4, & 5). Further 112 investigational studies are required to know if early treatment in such a patient could prevent stroke, as in our 113 case, even though he was tested positive, he was started on Covid-19 Treatment protocol only after he developed 114 stroke and repeat X-ray showed B/L pneumonia. Although Serology workup for Lupus anticoagulant came 115 positive on the repeated second with negative anticardiolipin and negative anti Glycoprotein, the underlying 116 antiphospholipid syndrome (APS) is still suspicious considering the high rates of false positives rates of lupus 117 anticoagulant, and the presence of Lupus antibodies (aPL) in other settings including infection, bacterial/Viral, 118 Medications, Malignancy besides APS, either transiently or persistently [7]. McNally T,8, in his report, "The 119 use of an anti-beta 2-glycoprotein-I assay for discrimination between anticardiolipin antibodies associated with 120 infection and increased risk of thrombosis," concluded that the alpha-beta 2GPI assay is harmful in patients 121 with transiently positive ACL assays associated with infection. We plan to repeat the Anti-lupus anticoagulant 122 test after 12 weeks. However, it would be interesting to know if Covid-19 disease does increase the occurrence 123 of Anti-phospholipid syndrome and related thrombotic events. Though limited data of just 6 cases of COVID 124 infection-related large vessel stroke, including ours, Anterior circulation (ICA/MCA) is the most common site of 125 thrombus occurrence. In contrast, just one case involving posterior circulation is reported in the cases described 126

127 by Oxley TJ et al6.

Financial support and sponsorship: No funding was acquired for this paper. Consent for publication: Consent for publications were taken from patient and all respective departments.

Though Oxley et al6, in his case, reported complete resolution of the thrombus after ten days of anticoagulation, our situation was complicated with the recurrence of thrombus the next day. We plan to repeat DSA after four

135 weeks of anticoagulation treatment.

136 .2 VIII.

137 Learning Points/Take Home Messages

138 ? Large Vessel thrombus in Covid-19 positive patient could be a new etiology of stroke. ? The association

between the Inflammatory peak, the formation of thrombus, and stroke occurrence need to be further investigated.? Along with the effectiveness of anticoagulation and early treatment of Covid-19 infection in preventing such

141 stroke is yet to be determined.

¹⁴².3 Conflict of Interest:

143 All authors declare no potential conflicts of interest to disclose related to the publication of this case series.

Author Contributions: KM, AH identified the cases, obtained informed consent and wrote the initial manuscript. MMK assisted in the literature review and manuscript writing. AH reviewed the case as infectious disease experts. Rest contributed to the manuscript writing, literature review and discussion. was also involved in image selection and critically revising the manuscript to its final form. All authors approved the final version for submission.
