20

21 Index terms—

²² 1 Introduction

fter nearly forty-two years in practice, this is a short summary of experience from our institution and also from other centers; and, especially, incorporating experiences from other colleagues, so that the idea is to share valuable stories, circumstances, and knowledge. Therefore, this paper may become a source of reference as an aid when working in this quite demanding medical and surgical specialty.

The circumstances herein described may have occurred in many centers and institutions, and we must remember that communicating and sharing our experiences may prevent the occurrence of undesirable events.

This paper is an update of a previous article that was published nine years ago. New topics that are part of our current practice have been introduced and developed. Perhaps there are not many references since this is not

a strict scientific document or a rigorous research project or a paradigmatic icon in Obstetrics and Gynecology.

The decision for preparing and updating this paper was based on the generous reception it achieved in different academic meetings, including symposia of the Peruvian Gynecology and Obstetrics Society, our latest National

Congress; and particularly, on requests made by many dear friends and junior specialists who are so eager to

learn from the experience of us, senior practitioners.

For a proper start, the four cornerstones of modern medical ethics will be introduced (Belmont Report, April 18th, 1979) and then things that MUST NOT BE DONE in Obstetrics and Gynecology will be developed.

38 **2 1**.

39 No Maleficence: This means never causing any deliberate harm to patients under our care.

3. Beneficence: Our actions must be solely directed towards doing the best for our patients, aiming to achieve the best benefit for all of them.

42 4. Justice: All patients must be treated equal, no matter their social condition, religion, economic status or 43 any other particular consideration.

44 **3** Coffee consumption:

It is not advisable the surgeon has an excessive intake of coffee, dark tea, or alkaloid containing energizing 45 beverages or soft drinks, prior to a surgical procedure, particularly if delicate procedures such as microsurgery 46 are to be performed. Most soda drinks contain caffeine. Alkaloids may exacerbate adrenalin and endorphin 47 production and they reduce the capability for performing fine movements. A good choice is to drink decaffeinated 48 coffee or caffeine-free soda (1), (2). 6. Air exchange. Never miss having air exchange in the Operation Room 49 (OR), aiming to reduce and prevent infections. Exchange must consist of using 15 times the total environmental 50 air volume for every hour we may spend in the OR. Good quality air extractors and air conditioning devices 51 must be available. Surgeons performing open surgical procedures, or any other procedure type should not 52 transpire, since there is likelihood that sweat droplets may reach the operative field (3), (4). 7. Antibiotic 53 prophylaxis. This measure must not be abused. Many studies, including some performed in our institution have 54 shown that in elective surgery, patients undergoing adequate pre-surgical preparation have the same likelihood for 55 developing any infectious complication compared with those that had received antibiotic prophylaxis, including 56 those undergoing vaginal or abdominal hysterectomy or those undergoing a cesarean section (??), (??), (?), (8). 57

58 Antibiotic misuse or abuse leads to the development of multidrug-resistant microorganisms.

⁵⁹ 4 NSAIDS in the immediate postoperative period.

Analgesic agents that may lead to coagulation alterations must not be used, at least during the first 24 hours after pelvic surgery. The use of opiate derivatives is a preferable choice. The rich venous network and abundant vascular plexuses in the pelvis must be considered, in which the only hemostatic action we could take is compress affected tissues, without using vascular ligation or cauterization.

9. Appropriate dressing in the Operating Room. Hair from the head and other areas, as well as the nose, 64 must always be covered with a cap, mask, and gown. If exposed, hair may contaminate the surgical area and the 65 immediate surrounding environment. Some female or male doctors misuse their caps by allowing some portions 66 67 of their hair to be exposed, just as if they were participating in beauty contest; which may be a reflex of their 68 own insecurity on their physical capability (and also intellectual disability?) for attracting the opposite sex. Sometimes, their nose is not adequately covered, and maybe they ignore the number of microorganisms currently 69 residing in this area. The larger the nose is, the larger the number and presence of potentially pathogenic 70 microorganisms. The Operating Room and the Surgical Center are not a place for having an affair. These are 71 places for saving lives, and for alleviating and cure patients. The most serious situation is that such behaviors 72 may constitute a negative paradigm for all involved personnel. We are healthcare professionals, independently 73 74 of sex, and no matter how good looking we are or not. 16. The importance of bipolar forceps. No endoscopic gynecological procedure should be done without having adequate spare bipolar forceps. These devices are so useful 75 for hemostasis. Without their use, rates for conversion to laparotomy would be higher, with the consequent risk 76 77 for patients.

⁷⁸ 5 Menses during gynecological surgery.

No gynecological surgery procedure should be performed, whether open or laparoscopic if the patient is menstruating (do not consider cases of abnormal uterine hemorrhage), since problems with bleeding and hemostasis may become more severe, because of the physiological alterations occurring in the coagulation cascade during this time period in women of child-bearing age (10).

18. Presence of a Foley catheter. Do not forget to place a permeable Foley catheter in the urinary bladder during the whole surgical procedure. Therefore, lesions in an empty bladder are prevented, and the pelvic operative field is widened, reducing the likelihood for affecting structures like the ureter and the intestines, on top of the urinary bladder.

19. Preoperative assessment. No surgical procedure should be started without having previously met the patient and without having performed a thorough physical examination. This latter procedure defines the type of incision to be made, the procedure type, or withhold the surgical procedure because of an inappropriate indication. Many times, some surgeons operated patients assessed by other colleagues with indications for excising cysts or fibromas; and when cavities were explored, none of such 'tumors' were found.

92 6 Intravenous access for fluid administration.

No surgical procedure should be initiated without having a proper intravenous access. This is crucial for rapid
fluid or blood replenishment. This is a lifesaving procedure.

21. Patient relaxation. A poorly relaxed patient must never be operated. We must request the anesthesiologist to have the patient completely relaxed, particularly for laparoscopic surgical procedures, unless it may be a matter of life or death. Having a patient perform Valsalva's maneuver during the surgical procedure where crucial steps are being taken, would not be feasible and it would be very risky for all.

22. Introducing Veress needle. The introduction of the Veress needle is to be taken so seriously when we are about to insufflate the abdomen and produce pneumoperitoneum for a laparoscopic surgical procedure. We must be so careful, since subcutaneous emphysema may occur, a blood vessel may be perforated, or an organ may be damaged. 23. Adequate pneumoperitoneum. The abdomen must never be inadequately insufflated when entering for the very first time in a blinded fashion while performing videosurgery. Insufflation must be adequately performed, or no insufflation is done, and then open surgery is to be performed. There are some reports of aortic perforation occurring in such circumstances (11).

106 24. Gas from pneumoperitoneum. Do not use oxygen or gases that may unfavorably affect patients when 107 laparoscopic surgery is performed, even if they were less expensive. Oxygen is a good electricity conductor and 108 it may inadequately conduce an electric spark. Other gases may compete for patient's oxygenation and lead to 109 deleterious effects. The most adequate measure is to use carbon dioxide (12).

¹¹⁰ 7 Auxiliary instruments in videosurgery.

Auxiliary instruments, such as uterine manipulators, fixing forceps, separators or dual valves for irrigation must 111 not be left apart. Some persons think that by using less instruments they might become better surgeons. They 112 might be skillful, but they may not be working under comfortable conditions and then they may place patients 113 at an avoidable risk. This arrogant act is against the principles of medical ethics. Adequate instruments for each 114 circumstance must be properly used. 26. Horizon when doing videosurgery. When performing laparoscopic and 115 hysteroscopic surgery, the horizon line and/or the tridimensional space must never be lost. We must demand 116 that the cameraman follows the action maintaining these vital reference points. By doing so we will not lose 117 the anatomical perspective and we will avoid having lesions in different organs and systems. Because of losing 118 perspective and horizon, ureteral, bladder, and intestinal lesions have been reported. There have been cases in 119 which bladder perforation has occurred, with invasion of the wide ligament, crossing the uterine wall. 120

121 27. Dorsal aspect of Fallopian tubes. When performing Fallopian tube surgery, it is important not to forget 122 that the dorsal aspect of Fallopian tubes is the less vascularized area, and there is the place where the procedure 123 may be safely performed. 28. Usefulness of irrigators in videosurgery. Do not forget that irrigators they also are 124 helpful in dissection and not only for irrigation and aspiration.

125 The technique is called hydrosection, and this must be mastered by every laparoscopy specialist (13).

¹²⁶ 8 Abdominal incision in case malignancy is suspected.

No transversal incisions should be made when opening the abdomen when there is strong suspicion on the presence
 of a malignancy. Cancer staging or cytoreduction may become more difficult by doing so.

30. Gauze in surgery. Folded gauze packages must not be opened, since small pieces of thread may be left in the abdominal cavity, and these materials may become pyrogenic compounds. These should never be dragged when

cleaning the area, since they may cause lesions in vascular structures and enhance the formation of adhesions.

31. Gauze in microsurgery. Never use dried gauze when performing microsurgery procedures. Gauze shouldalways be humidified for use, even when solely used for hemostasis.

¹³⁴ 9 Aid in videosurgery.

When performing laparoscopic surgery and microsurgery, you should never operate with an assistant that might have no idea of the anatomical area to work with and/or who is poorly trained. This becomes of paramount importance when they are starting their learning curve.

¹³⁸ 10 Coagulation and cauterization in Endoscopic

Surgery. When working in endoscopic surgery, blood vessels and tissues must not be sectioned without prior cauterization. Should this not be the case, these structures may bleed and sometimes it is so demanding to stop all bleeding. being worked with, their destruction must not be superficial. Their whole depth implantation must be reached unless the implants are located upon a hollow viscus and risk of perforation may supervene. In such cases, management may incorporate complementary medical therapy (??6), (17).

39. Uterine tumors and videosurgery. Do not intervene on uterine tumors that are extrapelvically located according to videosurgery, if no electric morcellator is available. Doing morcellation using a vaginal approach with such tumor means putting the patient at risk; and if a decision is made for using a vaginal approach, ad-hoc instruments must be readily available, including a special bayonet.

¹⁴⁸ 11 Decision for conversion.

Neither folly nor silliness should prevail for deciding of converting a laparoscopic to an open surgical procedure.We must always think about the patient.

41. Fallopian tube microsurgery. We must never leave less than 4-cm of the Fallopian tube in case of performing reconstructive surgery. If in the projection the tube is less than 4-cm long, surgery must not be scheduled or attempted. Such tubes will never work, or they will be site for a future ectopic pregnancy (18).

42. Simultaneous videosurgery procedures. Do not miss combining hysteroscopic resection of deep seated myomas with simultaneous videolaparoscopy control, aiming to monitor the hysteroscopic procedure in order to prevent uterine perforation.

43. Importance of anatomical markers. We must not operate without knowing the anatomical markers of vascular, ureteral, and bladder crossings as well as those for all plexuses.

14 SUPRAPUBIC AMNIOCENTESIS IN PRETERM PREGNANT

44. Hypogastric or internal iliac ligation. We must not miss the technique for hypogastric (blood vessels) ligation. Every pelvic surgeon who respects himself/herself must master the technique for locating and ligating hypogastric arteries. We must remember that these arteries downstream become uterine arteries. They are also known as internal iliac arteries and their anatomical marker is the obturator fossa or foramen, in the vicinity of the ureter.

164 **12 45**.

Washing the abdominal cavity. Avoid not performing thorough washing of the abdominal cavity. Not less than 8liter fluids or saline solution should be used when washing a cavity, especially if a perforation of a cystic teratoma had occurred, because of the risk for the development of chemical peritonitis. This washing procedure must be performed both in open surgery as well as in laparotomy.

46. Surgical approach for an abdominal malignant tumor. Videosurgery must never be performed when there is strong suspicion that the ovarian tumor (to be operated) is a malignant neoplasia. In such cases, an open procedure with a median incision is preferable.

47. Preventing pelvic adhesions. Because of not leaving enough fluid or because of leaving clot residues. When a small amount of fluid or clots are left in an unpolished surface, the generation of adherences is enhanced.

48. Relationship between intraabdominal pressure with hemostasis. Do not review hemostasis excessively reducing intraabdominal pressure when finishing a laparoscopic procedure. The intraabdominal pressure should be reduced to 7-mm Hg. With this level, collapse of both venules and arterioles that might bleed when taking cannulas and the laparoscope tube out is prevented.

49. Reviewing the places where trocars are inserted. We must never miss reviewing the places where intraabdominal trocars and cannulas for videolaparoscopy have been inserted when the procedure is over, in order to determine whether a hematoma had been formed or if there is any bleeding. 50. Assessing the uterine cavity during hysteroscopy.

While performing a hysteroscopy we must never explore using optics or during the introduction. The exploration must always be performed taking out the optics, after reaching the end of the cervix we introduce the instrument once again until touching the uterine fundus, exploration is reinitiated, and the procedure is repeated as many times as necessary.

By respecting this technique, we will avoid perforation accidents. Surgeons overestimating their capability are those who have accidents, that is not the case with those who recognize their limitations. must not be released using curettes. Uterine synechiae must be released using an adequate resectoscope for such circumstance during direct vision hysteroscopy, and it is much better to have appropriate scissors available.

¹⁹⁰ 13 Medical Research

191 52. Time for correcting cystocele during TOT suspension. Perform TOT (Trans obturator Tape) suspension 192 not having corrected cystocele (19). Emmett needles must never pass through the obturator fossa for sling 193 placement, without previously having corrected urinary bladder prolapse, since likelihood for having urinary 194 bladder perforation is increased; also, it will be more difficult to establish the ideal stress aiming to suspend the 195 ureterocele with a sling or a mesh in order to avoid stress urinary incontinence.

53. Fetus in transverse dorsal anterior position with premature membrane rupture. Transverse hysterotomy must not be done in those cases showing the fetus in a transverse position with its dorsal part facing forward and membrane rupture. The likelihood for failure when attempting fetus extraction is so high and the incision would have to be extended or another incision might be performed. The likelihood for tearing the uterine segment and hemorrhagic complications is much higher. There have been reported cases that ended in hysterectomy. The adequate procedure is to perform corporal hysterectomy.

²⁰² 14 Suprapubic amniocentesis in preterm pregnant

women. Suprapubic amniocentesis must not be performed in preterm pregnant women. This procedure should
be done using other approach and always under ultrasonography guide. If a suprapubic puncture is performed,
the likelihood for premature membrane rupture is very high.

55. Forceps, vacuum, and cervical dilatation. Forceps or vacuum must never be used if the cervix is not completely dilated. The likelihood for the occurrence of cervical and segmental tearing is increased, and the baby may get hurt (20) ??3), (??4), (25).

66. Informed consent: Never miss explaining the procedure stating all its benefits and consequences; also, make the patient and her spouse sign the informed consent before performing any intervention (26), (27). 67. Voluntary withdrawal: If at any time while the patient is hospitalized, she refuses any procedure of therapy; it is important not to sign her discharge; instead, prepare a 'voluntary withdrawal' document to be signed by the patient in the presence of witnesses. Therefore, when the physician discharges the patient, it is under her responsibility (28), (29).

10.34257/GJMREVOL20IS8PG41

²¹⁵ 15 Covid-19 pandemics:

It is important to comply with social distancing, properly using a face mask and to constantly wash your hands
 (30), (31).

²¹⁸ 16 Social distancing for physical examination in the

219 Covid-19 pandemics: It is not possible to comply with physical examination for all patients. Therefore, we must

- NOT receive patients with fever, those reporting contact with Covid-19 affected people during the last two weeks prior to the visit, those not using a face mask or those who may present with an evident NON-gynecological
- 221 prior to the visit, those not usin 222 physical involvement (30), (31).

²²³ 17 Asymptomatic pregnant women with Covid-19:

- 224 We must never forget that there may be a significant number of pregnant women that might have asymptomatic
- 225 Covid-19 infection (32), (33), (34).

²²⁶ 18 Vaporizer use, Covid-19:

- Prior to the consultation, it is convenient to vaporize patients with fifth generation quaternary ammonium for sixty seconds.
- ²²⁹ This compound may eliminate viruses, bacteria, and fungi. 72. Personal protection equipment withdrawal:
- 230 DO NOT FORGET that the moment with a maximum likelihood for transmission occurs when taking out the
- protective equipment, such as face protectors, gloves, coats, face masks, etc. (30). So, we reached the end of this
- ²³² paper. Anyway, we are so happy that we did not find further data in our reference and experience bank. We hope this paper is helpful for you and especially for patients, who still are our reason for doing a good job. ¹

Hysterotomy while performing myomectomy. No uterine corporal incisions should be made in case a myomectomy is performed. Transverse incisions are preferred since they lead to less bleeding and they also lead to less adherence formation. Although some cases have been reported where no transverse incision could be made, because of concern with respect to affect tubal ostia or because of the tumor localization.

[Note: ? Cut Down Tissues or Vascular Pedicles During Endoscopy without Having Performed Electrocoagulation ? Dissect Tissues without Having Identified Cleavage Planes. 34. Dissection planes. Do not leave cleavage planes unidentified. Otherwise, dissection may become difficult with plenty of bleeding.35. Septic foci when performing high-complexity fertilization procedures. Septic foci in laparotomy (hydrosalpinx, ovarian microabscesses) must never be left when performing laparotomy prior to a highcomplexity fertilization procedure. These structures or tissues are embryotoxic, they maintain the presence of endorphins that reduce pregnancy viability(14).]
