6 Abstract

2

3

⁷ Either general or regional anesthesia can be used for spine surgery. Spine surgery involves

⁸ acomplex procedure. The aim of a spine surgeon for doing a good surgery requires a clear and

⁹ bloodless field especially in procedures done under microscope. As the working space is less a

¹⁰ small epidural bleed can cause further complications in surgery. Another aspect is to take care

¹¹ of post operative analgesia which is better achieved with regional anaesthesia. Regional

¹² anaesthesiahas many benefits, namely less time, lower incidence of nausea and vomiting

¹³ ,general hazards of general anaesthesia can be avoided and cost effectiveness. This article

¹⁴ reviews effect of regional anaesthesia on lumbar spine surgery.

15

16 Index terms— anesthesia, general, spinal, lumbar surgery.

17 **1** Introduction

n acceptable anesthetic technique must have characteristics such as rapid onset and reversal of effects, it must
maintain stable hemodynamic during operation without need to increase blood transfusion and an excellent
anesthetic must decrease recovery room stay while reduce postoperative pain, nausea, vomiting, and requirement
for additional analgesics.

22 Surgery on lumbar spine can be safely performed under general or regional anesthesia. Patient's satisfaction 23 and the ability to carry out prolonged operations in the prone position without airway compromise are advantages of using general anesthesia (GA). Alternatively, the most important advantages of regional anesthesia are 24 the decrease in intraoperative blood loss and consequently improving operating conditions, the decrease in 25 perioperative cardiac ischemic incidents, postoperative hypoxic episodes, arterial and venous thrombosis, and to 26 provide proper postoperative pain control. Additionally, in order to prevent brachial plexus injury and pressure 27 necrosis of face, it is better if patients can position themselves while they are awake. This is possible only with 28 spinal anesthesia (SA). 29

Reviewing the medical literature, there are controversies whether regional or general anaesthesia offers these 30 advantages for lumbar spinal surgery. Sadrolsadat et al2 conducted a prospective study and showed that in 31 contrast to the previous studies that revealed spinal anaesthesia was better than general anaesthesia for patients 32 33 lumbar spine surgery, spinal anaesthesia had no advantages over generalanaesthesia. Their prospective study 34 showed that general anaesthesia has many advantages over spinal anesthesia. However, they recommend further 35 studies for elucidating the advantages of each technique. Scott et al 1showed, pulmonary complications were 36 more common in patients underwent GA compared with regional anesthesia. Two retrospective studies shown that SA resulted in better outcome compared with GA in patients underwent surgeries on lumbar spine 1,3,. 37

In our clinical experience, it seems that patients who underwent lumbar spine surgery with regional anaesthesia have less adverse effects and has more advantages as compared with general anaesthesia. This is in accordance with the most previous studies but is opposite to Sadrolsadat et al study.

41 A, little overview of lumbar spine disorders and various surgeries done for them is covered below.

42 **2** II.

43 **3** Clinical Features of Spinal Disorders

a) Intervertebral disc lesions Prolapsed discs: lumbar backache is one of the most common causes of chronic
debility. Acute lumbar disc prolapse or chronic degeneration with disc-space narrowing at L4/5 or L5/S1 are the
most common pathologies 3 .The annual incidence of low back pain is estimated at 5%, but only 1% develops
radiculopathy. 4 In acute prolapse, the disc may bulge beneath the posterior longitudinal ligament in the mid
line (central disc) or posterolaterally with consequent distortion of the spinal canal or nerve-root compression.

⁴⁹ 4 b) Surgical procedures for lumbar diseases

50 Microdiscectomy is the gold standard operative treatment for lumbar disc prolapse. The standard approach is 51 through a midline incision over the affected interspace with intraoperative radiographs to confirm the operative 52 level. A fenestration of the ligamentumflavum and, if indicated minimal laminotomy exposes the thecal sac and 53 transiting nerve root. Medial retraction of the root permits identification of the disc space and prolapse and 54 subsequent discectomy. The patient is placed prone or kneeling.

There are various names and terms used for the numerous surgical procedures used to achieve surgical decompression by removal of the offending tissue whilst maintaining stability from facet joint or ligamenttumflavum hypertrophy. However, people who have had either standard discectomy or micro-discectomy have reported similar improvements one year after surgery. ?? Lumbar laminotomy and laminectomy:

laminotomy (partial removal of vertebral lamina) or laminectomy (complete removal of spinous process and 59 bilateral lamina and removal of underlying ligamentumflavum) are performed to decompress the spinal cord 60 and/or nerve roots via a posterior approach with the patient lying prone. Discectomy may also be necessary, the 61 dura is retracted to one side and the disc removed piecemeal. Extension of bony removal to include upto 1/362 rd of the medial aspect of the facet joint (thus maintaining stability) will additionally decompress the transiting 63 64 nerve root in lateral recess performed alone and unilaterally. This latter decompression is often called medial facetectomy. In general, laminectomy/ laminotomy, with or without discectomy, is performed if there are signs 65 of nerve root compression; it is expected that the individual's symptoms will improve when pressure on the nerve 66 67 root is relieved. 10 During these procedures there is a risk of damage to both the dura and retroperitoneal structures (e.g. major vessels). The extent of the procedure depends on the underlying problem and may vary 68 from simple laminotomy for single nerve-root compression to decompression over several segments for spinal 69 canal narrowing. In such cases, a stabilization or fusion procedure (e.g. plate and screws) lemay also be required 70 71 (where multiple levels decompression and concern regarding post operative stability)

Vertebroplasty and kyphoplasty are similar medical spinal procedures in which bone cement is injected through 72 73 a small hole in the skin (percutaneously) into a fractured vertebra with the goal of relieving back pain caused 74 by vertebral compression fractures. It was found not to be effective in treating osteoporosis-related compression 75 fractures of the spine in the only two placebo controlled and randomized clinical trials 11 The patients in both the experimental and placebo groups of the blinded study reported improvement in their pain, suggesting that 76 77 the clinical benefit noted in unblinded trials is related to the placebo effect. It is a minimally invasive procedure and patients usually go home the same or next day as the procedure. Patients are given local anesthesia and 78 light sedation for the procedure, though it can be performed using only local anesthetic for patients with medical 79 problems who cannot tolerate sedatives well. During the procedure, bone cement is injected with a biopsy needle 80 into the collapsed or fractured vertebra. The needle is placed with fluoroscopic x-ray guidance. The cement 81 (most used as well) quickly hardens and forms a support structure within the vertebra that provide stabilization 82 83 and strength. The needle makes a small puncture in the patient's skin that is easily covered with a small bandage 84 after the procedure.

Percutaneous interspinous device Interspinous process decompression (IPD) techniques may offer a less invasive 85 alternative for microsurgical decompressive surgery in lumbar spinal stenosis. Several implants have been 86 introduced in the market. The Inspace (Synthes, Umkirch, Germany) is a new implant strictly designed for 87 percutaneous implantation with short operating times. Regional anaesthesia is better suited for this procedure. 88 c) Anaesthetic considerationslumbar procedures (excluding corrective surgery) Regional anesthesia and general 89 anesthesia are both applicable anesthesic techniques for spine surgeries. A retrospective analysis by Tetzlaff et 90 al. 12 demonstrated that spinal anesthesia was a safe and effective alternative to general anesthesia for elective 91 lumbar spine surgery with reduced perioperative complication rates. They concluded that spinal anesthesia could 92 be an excellent choice for lumbar spine surgery. A review article by De rojas et al 13 concluded that both RA 93 94 and GA are safe and effective techniques for lumbar spine surgery and that RA may prove a better alternative 95 than GA for healthy patients undergoing simple lumbar decompression procedures or for patients who are at 96 high risk for general anesthetic complications. 97 Preoperative: surgical procedures on the lumbar spine for disc problems are common. Any preoperative

Preoperative: surgical procedures on the lumbar spine for disc problems are common. Any preoperative
neurological deficit should be recorded in the patient's notes, especially if a regional technique is considered.
Generally, these patients are otherwise healthy and no special investigations are normally required.

Intraoperative: it is possible to perform simple lumbar procedures under local or regional (spinal or epidural) anaesthesia. McLain et al. 14 reported that regional and general anesthesia have similar effectiveness for performing elective lumbar decompression surgeries, and also regional anesthesia showed some advantages over general anesthesia, including improved perioperative hemodynamic stability, decreased analgesic requirement, and decreased occurance of postoperative nausea. spinal procedures the patient is placed prone or in the kneeelbow position. It is therefore advisable to use an armoured tracheal tube to minimize the risk of kinking and to ensure that the tube is well secured before and after turning the patient. Potential problems with the prone position are summarized in Table 1. Sukhen N Shetty et al 17 suggests that spinal anaesthesia can be given for prone surgeries and is as safe as for supine surgeries.

Any standard maintenance regimen is acceptable. However, blood pressure control is important, balancing 109 the need to ensure spinal cord perfusion with the requirement to produce a bloodless surgical field. Sodium 110 nitroprusside and esmolol infusions have been widely used for this purpose, though remifentanil is becoming 111 popular. Blood loss is usually minimal from simple procedures, though if extensive laminectomies and fusions are 112 performed, cross-matched blood should be available. A recent randomized clinical trial by Attari et al 18 revealed 113 that spinal anesthesia has adequate advantages over general anesthesia in providing postoperative analgesia and 114 decreased blood loss by preserving a better hemodynamic stability. These factors results in higher satisfaction 115 rates for the surgeon and patients. Spinal anesthesia may lead to a reduction in blood loss associated with 116 vasodilation and hypotension produced by sympathetic blockade and less distension of epidural veins resulting 117 from lower intrathoracic pressure Additionally, reduced surgical time and blood loss in spinal anesthesia were 118 119 reported by Jellish et al. 19 in a prospective study. Standard monitoring is appropriate for simpler procedures. 120 However, invasive blood pressure monitoring, a central venous pressure line and a urinary catheter should be 121 considered if deliberate hypotension is used or if the procedure is likely to be prolonged and involve large fluid shifts. Lumbar Spine Surgery Outcome: Effect of Regional Anaesthesia commonly PMMA, although more modern 122 cements are Several studies comparing spinal anesthesia and general anesthesia in lumbar disc surgery have 123 reported spinal anesthesia as the preferred method for lumbar spine surgery. [12][13][14][15][16] In relation, some 124 centers have been routinely performing regional anesthesia for lumbar laminectomy and discectomy. However, this 125 is seldom done in practice because of medico-legal concerns that any new postoperative neurological deficit may 126 be blamed on the anaesthetic technique. A general anaesthetic technique involving intubation and mechanical 127 ventilation is more usual. For all posterior Postoperative-(1) Pain: most spinal surgeries are painful and good 128 postoperative analysis is important. Local anaesthetic and opioid drugs can be instilled into the epidural space 129 before closing. More usually, however, a regimen including patient-controlled analgesia (PCA) combined with 130 regular oral/rectal analgesics is successful., Regional anaesthesia improved postoperative conditions of patients 131 due to decreasing pain and need to the analgesia. Hassi et al 20 showed that patient satisfaction was high with 132 133 a low level of complications in SA. Nevertheless, their study was retrospective and did not compare it with the other anesthetic techniques Two different mechanisms 21 can explain decreasing postoperative analgesic use in 134 the regional Anaesthesia. First mechanism is the preemptive effect of regionalanasthesia that reduces the pain 135 severity by preventing afferent nociceptive sensitization pathway. The second mechanism is probably existence of 136 some residual sensory blockade in regional anaesthesia. This is due to lagging of sensory recovery behind motor 137 recovery. 138

140 Medical Research

(2) Nausea and vomiting: Various studies have also shown that spinal anesthesia provided shorter anesthesia durations, decreased nausea incidence and analgesic consumption, blood loss and was associated with fewer total side effects in different orthopaedic sugeries [22][23][24][25][26]. Nausea and vomiting are already common problems that anaesthesiologists must cope with during the postoperative period. These symptoms appear to be associated with many factors such as age, gender, ASA, obesity, duration of anesthesia, use of volatile postoperative opioids.

(3) Neurological deficit: Pre operative documentation is very important (legally also). This could be caused by
the regional anaesthesia technique or the surgery itself. Neurological damage during surgery and anaesthesia is
not limited to the site of surgery.

150 ? Poor patient positioning: Paraplegia and quadriplegia have been reported as a result of poor patient 151 positioning.

152 ? Site of surgery: There are reports of patients with spinal disease who have suffered neurological damage 153 either at levels remote from the site of surgery or during surgery unconnected with their spinal disease. However, 154 neurological damage is more likely at or near the site of surgery on the spine. Risk factors and methods for 155 minimizing them are listed below. The 'wake-up test' 27 involves lightening anaesthesia at an appropriate point 156 during the procedure and observing the patient's ability to move to command. The technique requires practice 157 and adds to the duration of surgery. In addition, it provides information at the time of the wake-up only and 158 misses damage occurring at other times.

Neurophysiological monitoring using somatosensory evoked potentials (SEPs) provides a continuous picture and offers a more sophisticated approach. Electrical stimuli are applied to the lower limbs and appropriately placed electrodes can record cortical (SCEP) or spinal (SSEP) evoked potentials. The resulting trace can be analysed for wave amplitude and latency with respect to a reference 'time zero'. SCEPs are affected by anaesthetic induction and inhalational agents, opioids and local anaesthetic drugs, and interpretation requires care and experience. Nevertheless, a decrease in amplitude or latency unrelated to drug administration of 35-50%
is thought to be significant and indicate possible cord damage. However, even in skilled hands, interpretation
can be difficult and a 'wake-up test' may still be required.

SSEPs can be recorded from electrodes placed into the epidural space either percutaneously or during surgery SSEPs are affected less by inhalational agents, but are sensitive to temperature changes and local anaesthetic drugs. Their stability during anaesthesia allows them to be used with more confidence during surgery than SCEPs. Motor evoked potentials can be obtained by stimulating the motor cortex with a transcranial electrode and eliciting a response from the distal spinal cord, peripheral nerves or muscle. They have not been used extensively for spinal cord monitoring because they are more difficult to achieve and are sensitive to inhalational anaesthetic agents.

(4)Other post operative complications: Postoperative complications include persistent hypotension, haemor rhage, urinary retention, nerve root damage, and caudaequina syndrome (urinary/faecal incontinence, perineal
 sensory loss and lower-limb motor weakness).

difference is considered to be a consequence of the elapsed time needed to perform spinal anesthesia, which 177 is conducted in the block room instead of an operating room, and also having no missing time for extubation. 178 In the absence of satisfactory differences between spinal anesthesia and general anesthesia, cost, associated with 179 180 the duration, could be judged to be an acceptable reason to decide on an optimum option. Surgeons, have 181 typically focused on the single issue of maximizing operating room efficiency and have indicated that reducing waiting times plays an important role in solving this problem. In the absence of satisfactory differences between 182 spinal anesthesia and general anesthesia, cost, associated with the duration, could be judged to be an acceptable 183 reason to decide on an optimum option .It can be speculated that regional anesthesia may lead to greater 184 cost effectiveness in spine surgeries. However the individual decision process and the multi-disciplinary approach 185 for optimal treatment of the patients.

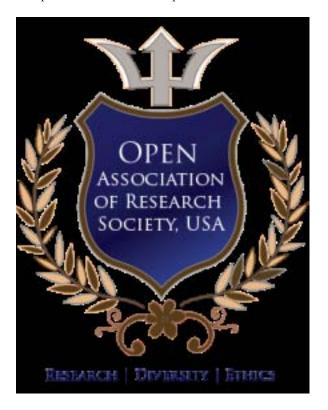

Figure 1: 7

stenosis. Less than 2% of symptomatic patients undergo operative treatment5.Surgical intervention is best directed at those with unremitting nerve root symptoms. Urgent surgical intervention is required in those with acute caudaequina compression or significant acute motor deficit (e.g. foot drop). However, urgent decompression once urinary retention and overflow incontinence has occurred seems to confer little benefit.6 Spondylosis: Recuurent disc prolapses can lead to lumbar disc degeneration resulting in flattening of the disc, facet-joint displacement, and a degree of instability with limited and painful movement. In addition to disc flattening, bony spurs may grow at the margins of the vertebral bodies, impinging on nerve roots and producing symptoms. Physiotherapy 7 is the mainstay of treatment, but in severe or refractory cases anterior spinal fusion may be the definitive option. Spondylolisthesis: changes, dysplasia or fractures of intervertebral facet joints may lead to forwards lipping of one vertebral body on the other. Levels commonly involved are L4/5 and L5/S1. Mostly asymptomatic, but the resultant loss of canal and foraminal diameter can both precipitate and accentuate symptoms of compression due to the other causes. Surgical treatment is based around decompression of the affected nerve roots. However, where instability is evident on standing flexion/extension plain lateral radiographs or anticipated, fusion may be undertaken. Spinal fusion provides stabalization and may be necessary for symptomatic relief. Minimally invasive surgical (MIS) techniques is used to achieve lumbar interbody fusion. The advantages of minimally invasive spinal instrumentation techniques are less soft tissue injury, reduced blood loss, less postoperative pain and shorter hospital stay while achieving clinical outcomes

procedure.. 8
